

# A Radio-Frequency Fragment Separator (RFFS) for FRIB

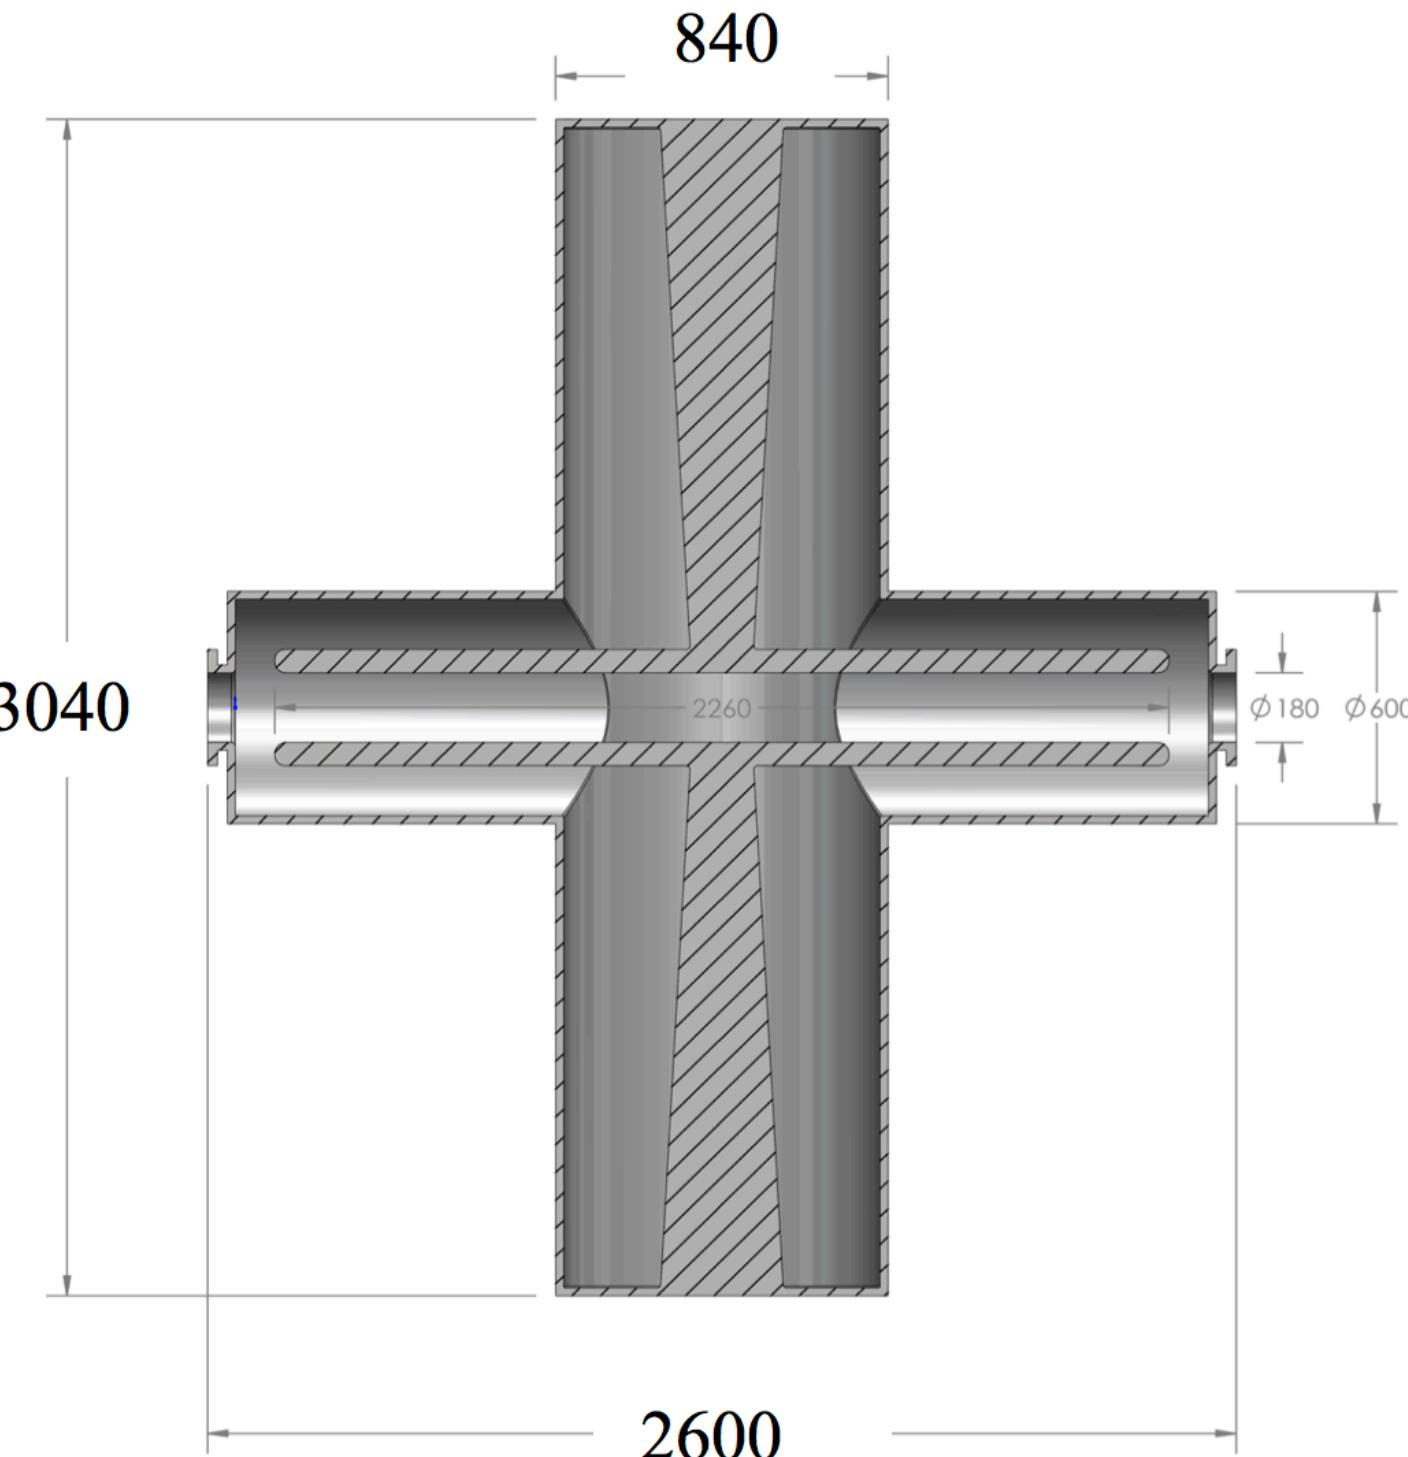

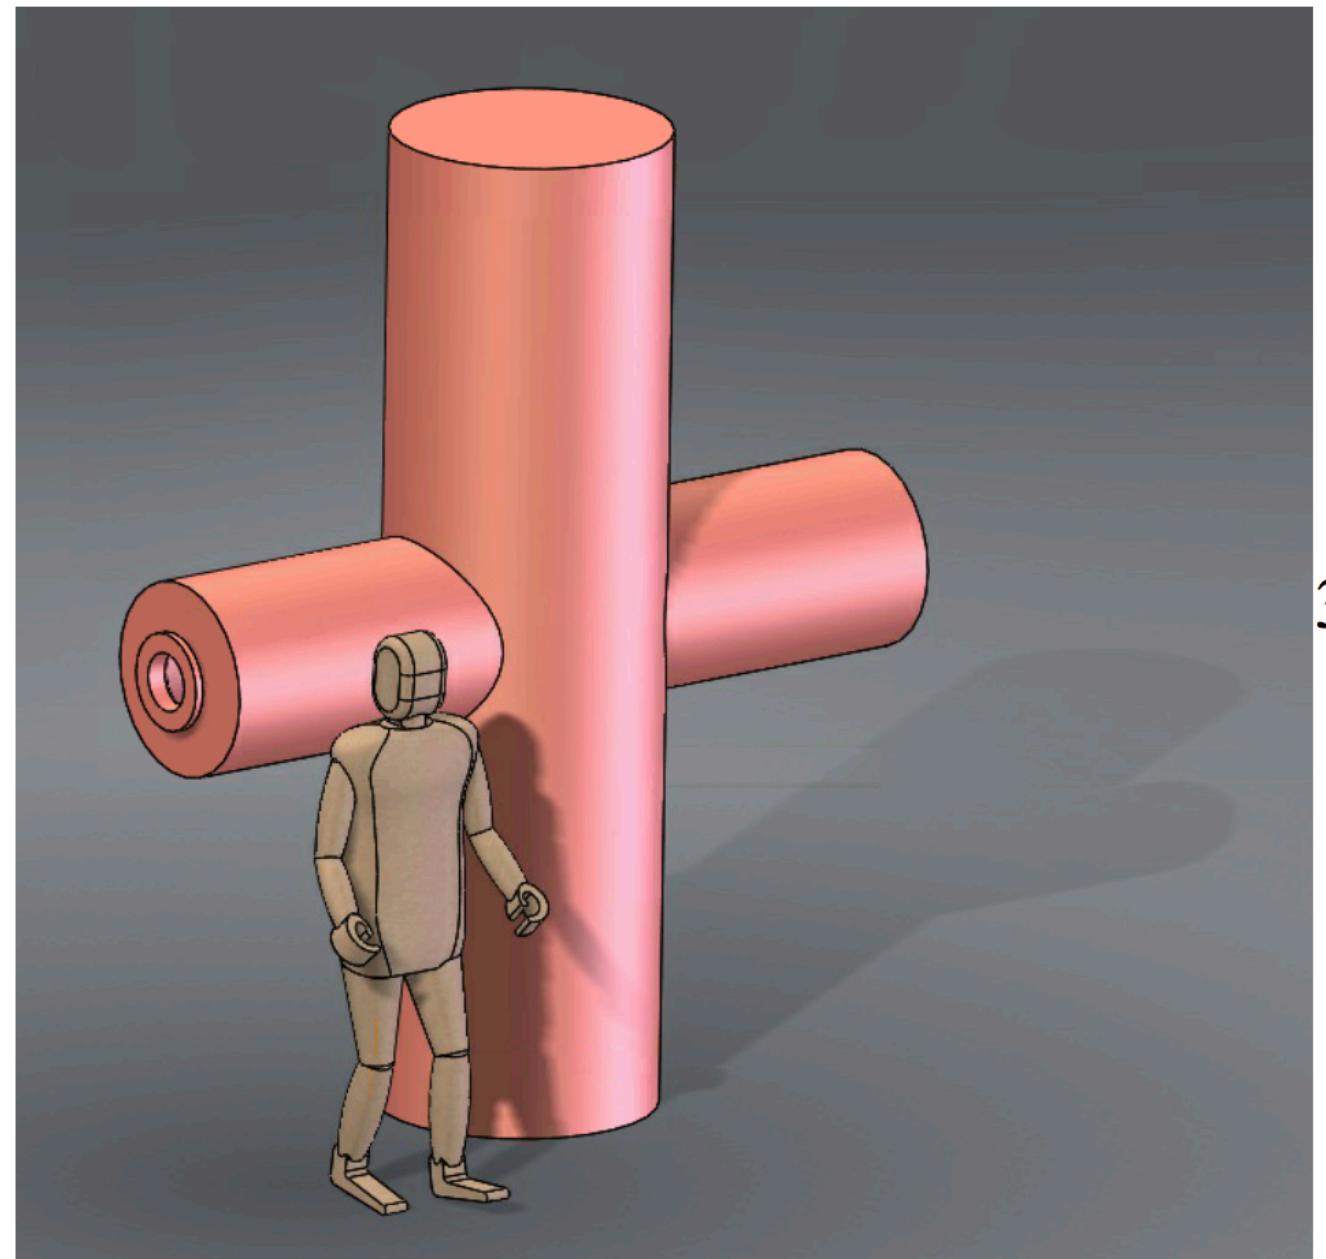

Daniel E.M. Hoff

*University of Massachusetts Lowell  
APS April Meeting – 04/15/2019*

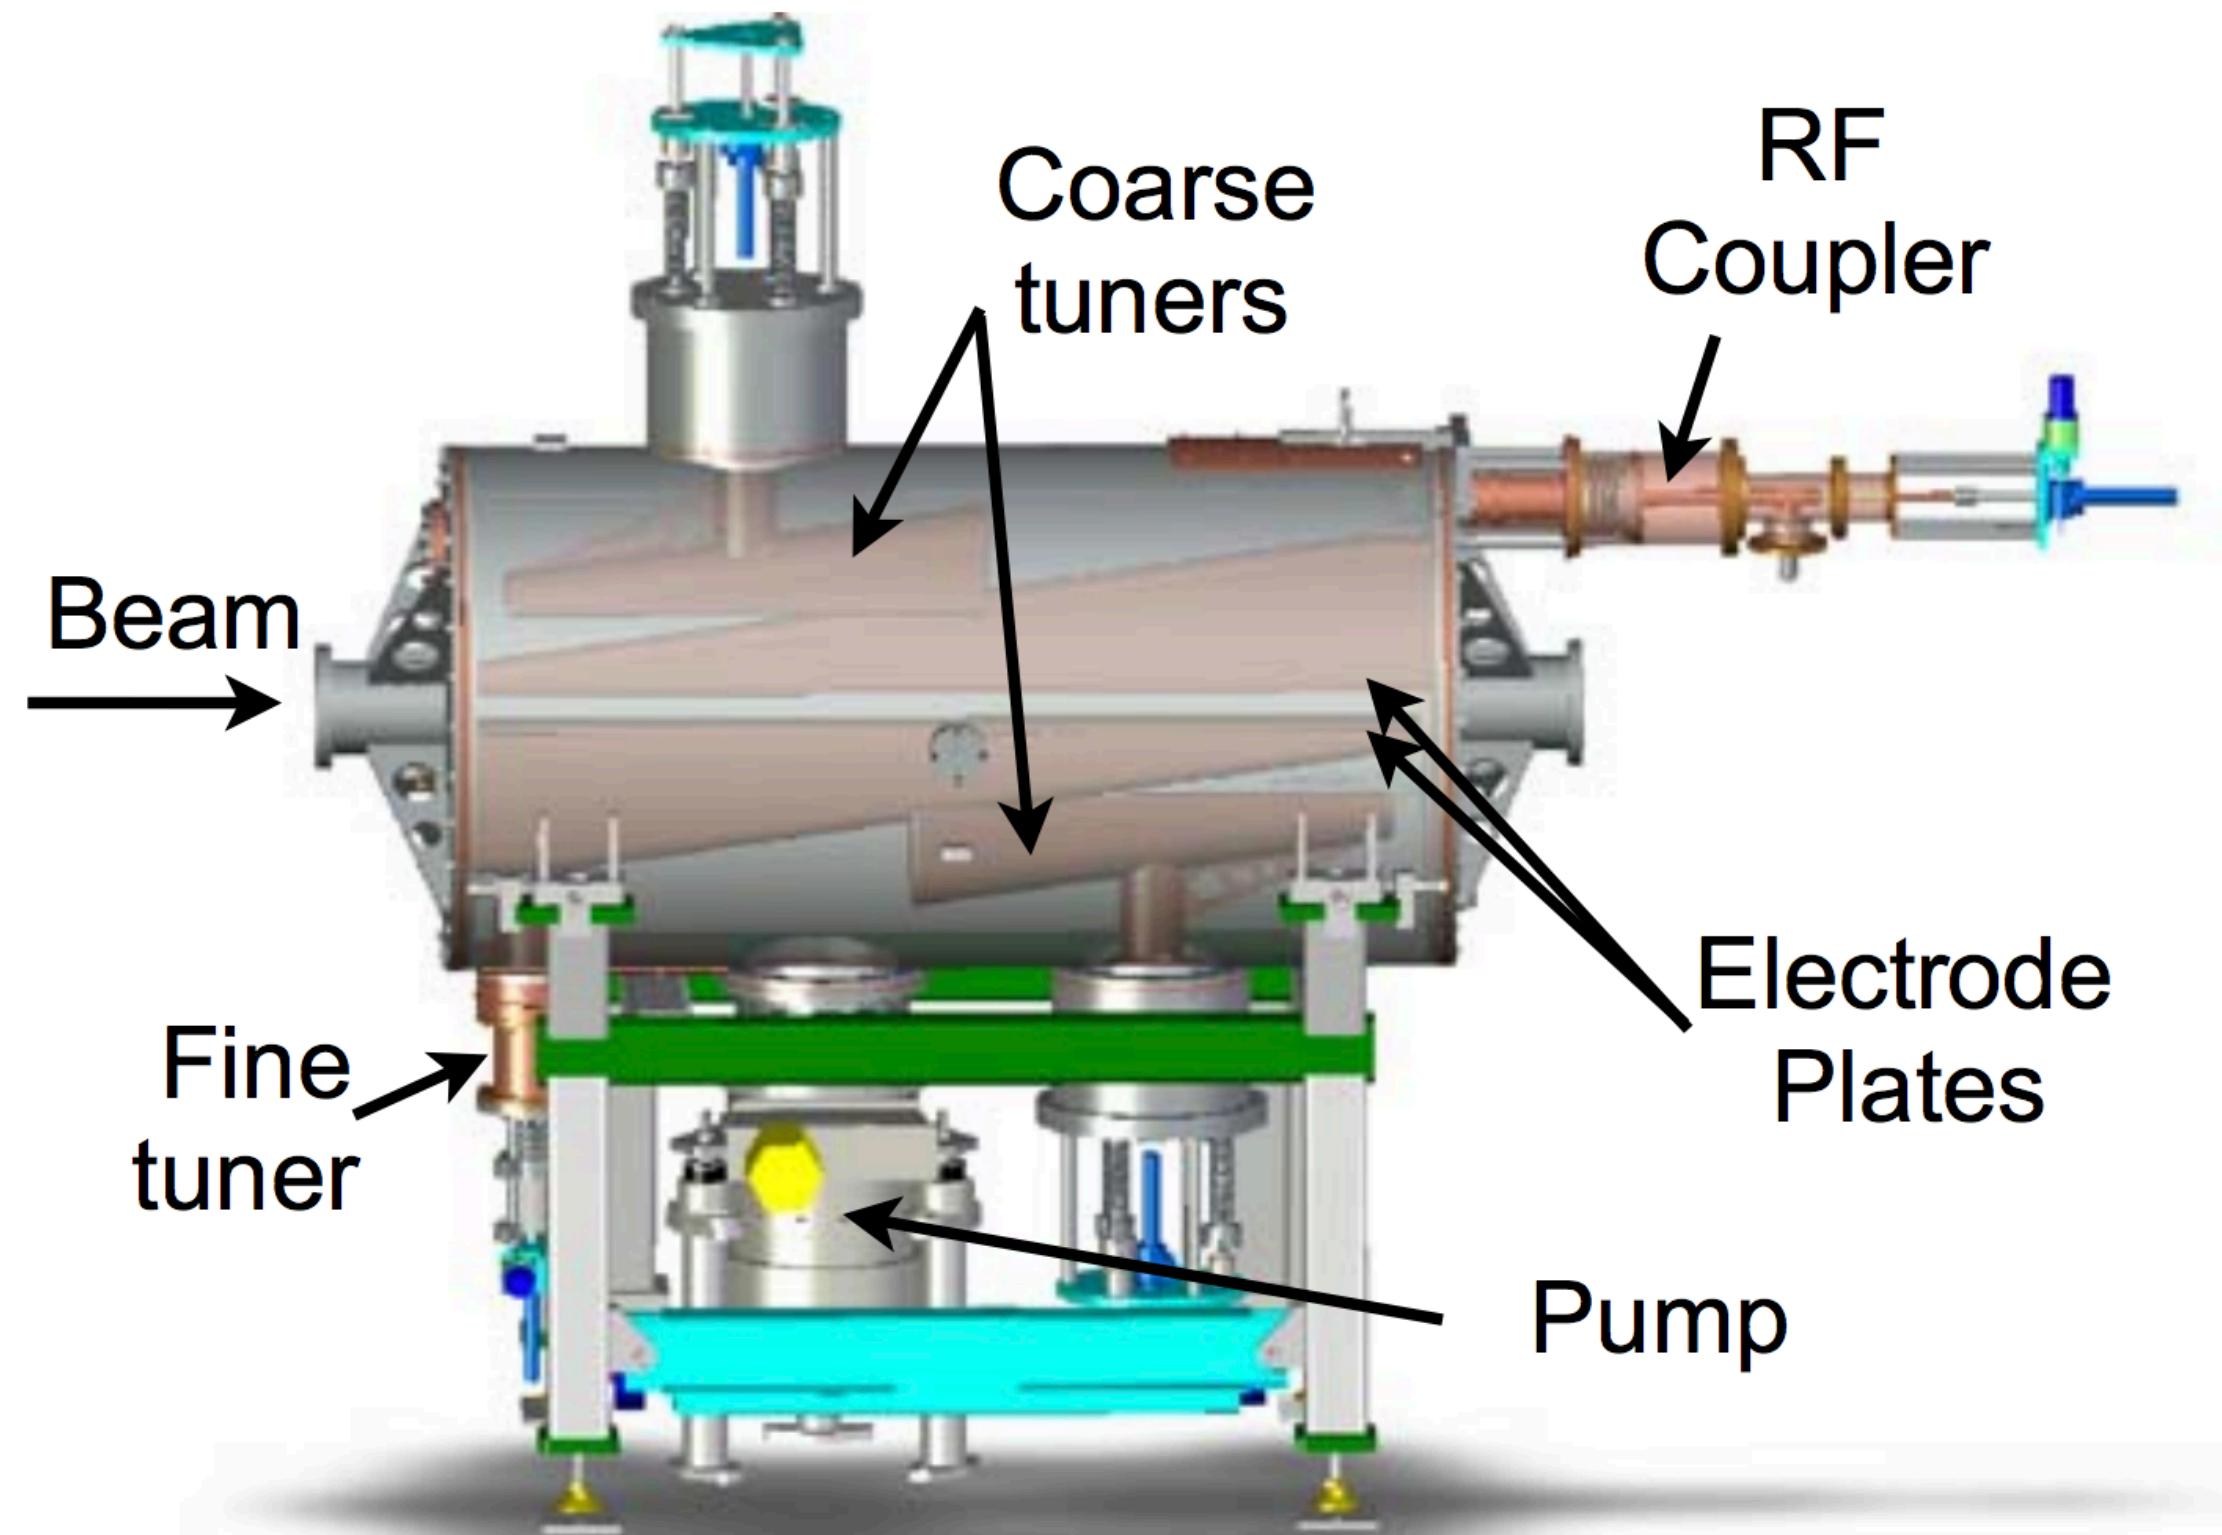

# Outline

- Capabilities of current RFFS at NSCL
- Experiments enabled by current RFFS
  - First observation of  $^{11}\text{O}$
  - $^{73}\text{Sr}$   $\beta$ -delayed proton emission
- Capabilities of proposed RFFS at FRIB
- Day 1 experiments at FRIB with new RFFS
  - $^{34}\text{Ca}$  2p decay
  - $^{72}\text{Rb}$  decay studies
  - $^{100}\text{Sn}$  decay studies

Length(m)	Gap(cm)	Peak Voltage(kV)	Frequency(MHz)	Q
2.26	18	150	20.125	12,900

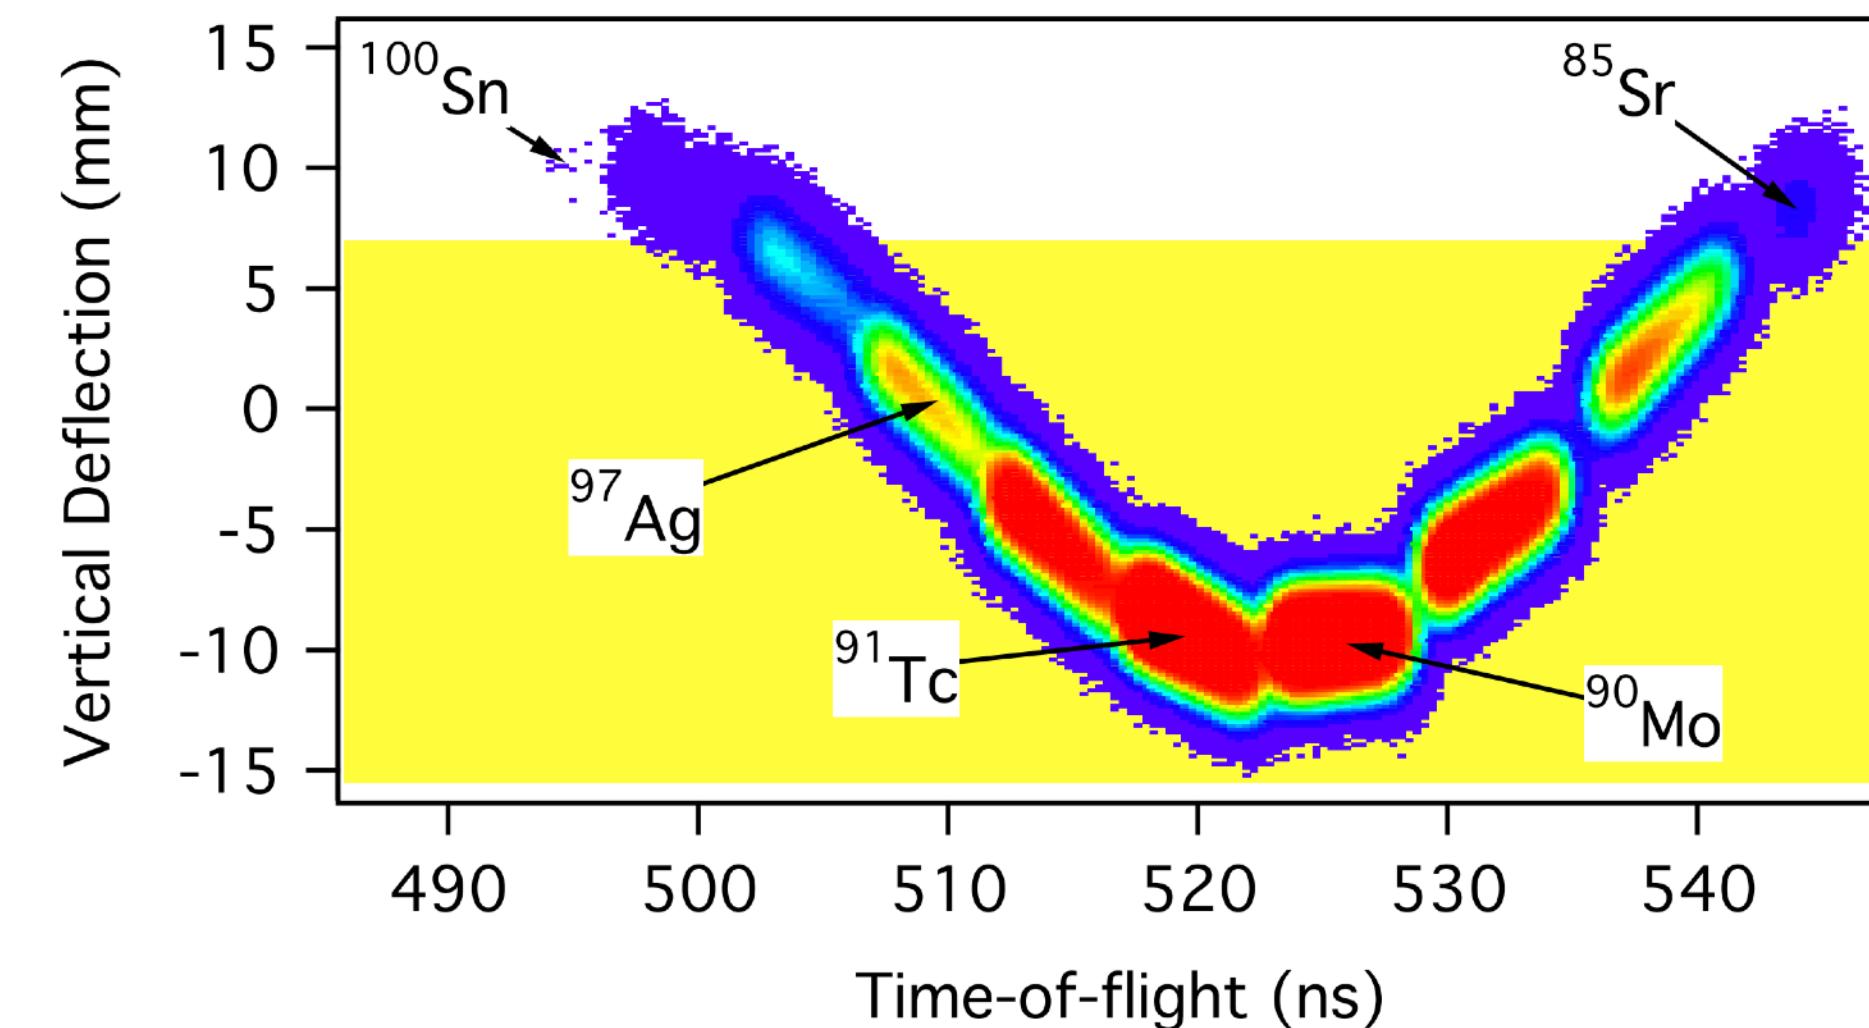

# RFFS at NSCL

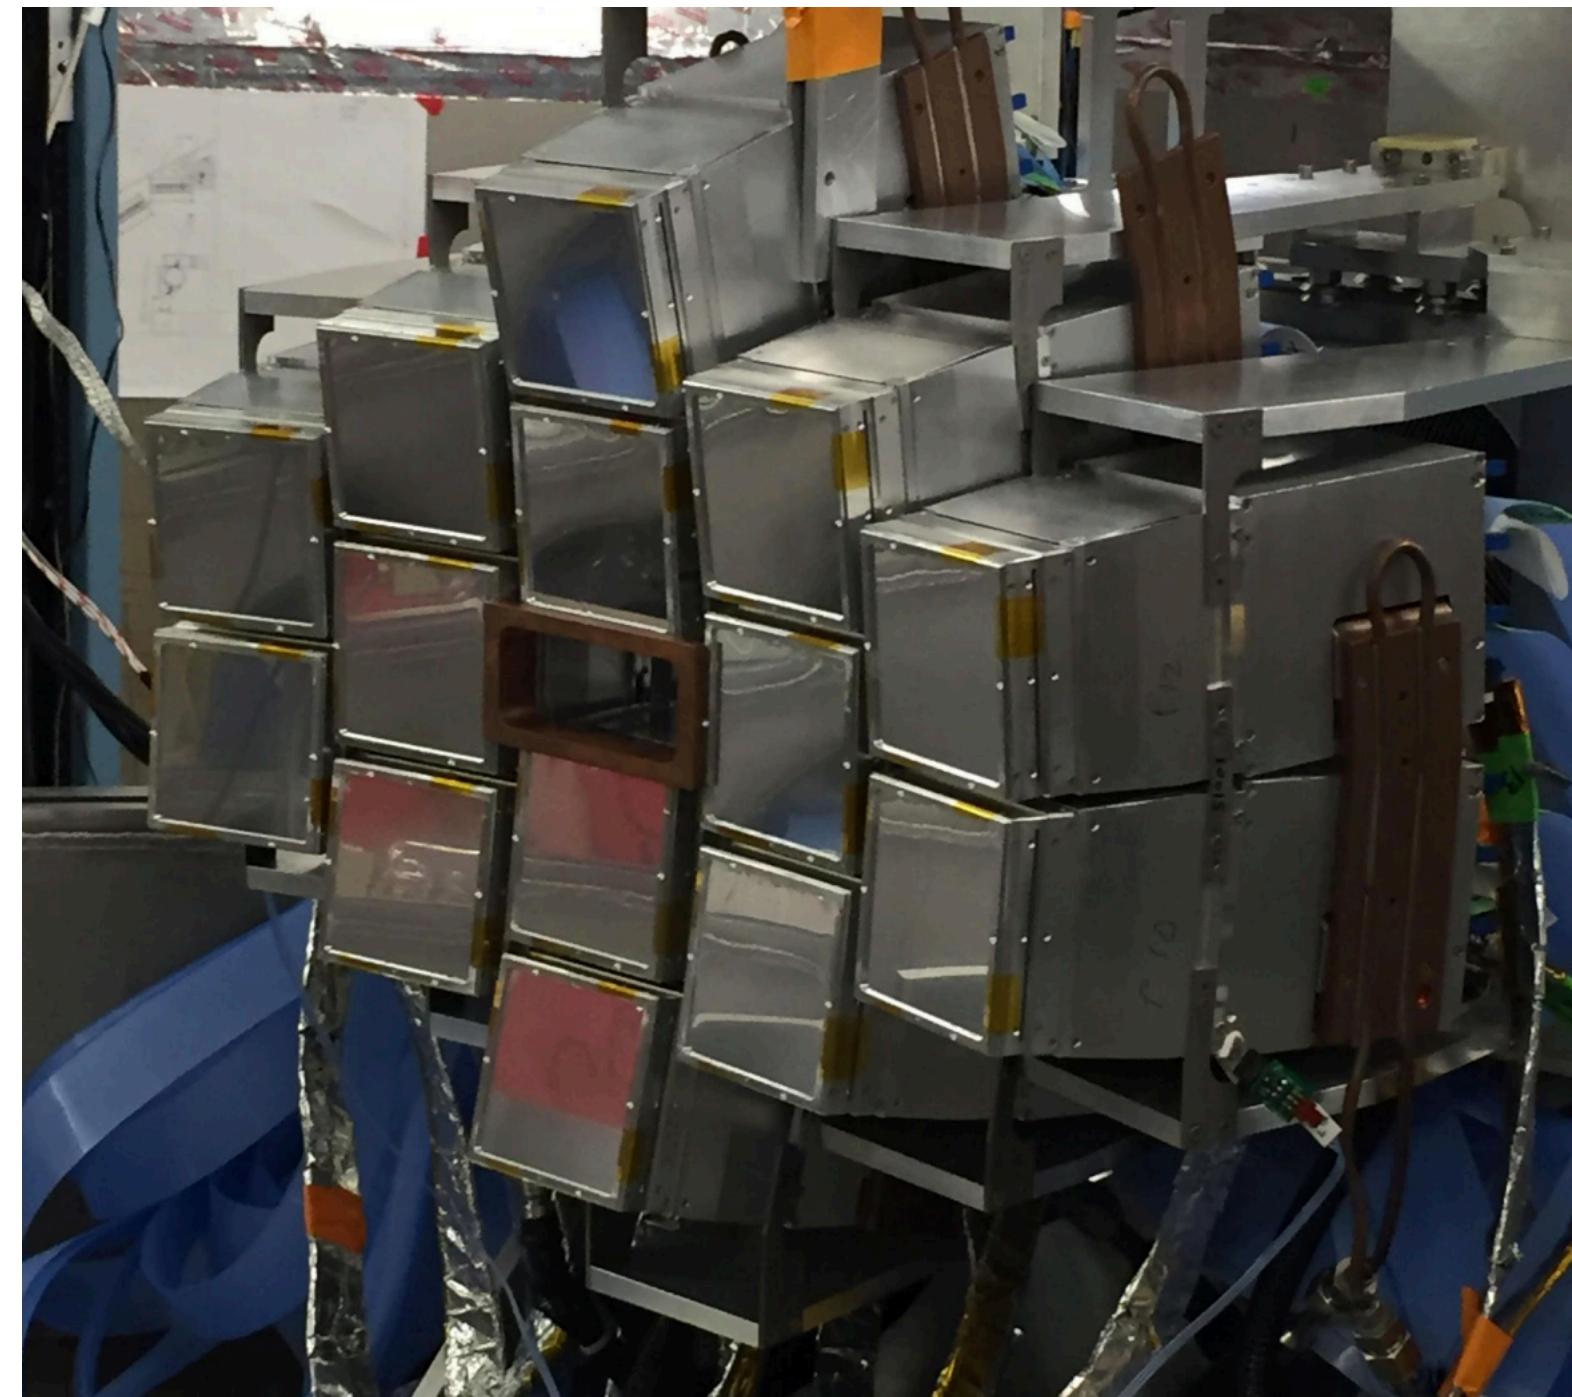

Length (m)	Gap (cm)	Peak voltage (kV)	Frequency (MHz)	<i>Q</i>
1.5	5	100	19–27	7500–10,000

D. Bazin et al., NIM A **606** (2009)

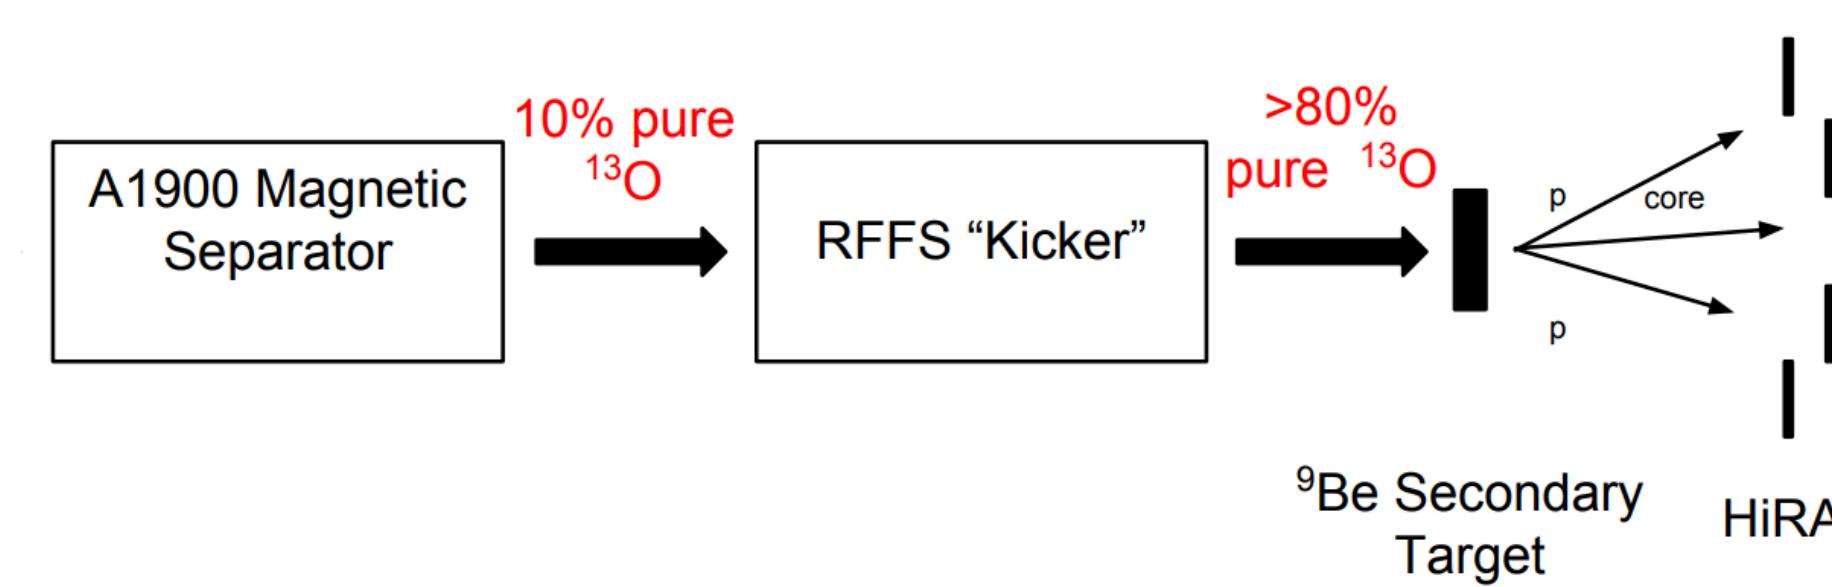

- RF Cavity tuned to around 20 MHz.
- Phase of RF is optimized to deflect ion of interest maximally.
- Other ions are blocked by slits, resulting in purification of beam.
- Greatly purifies proton-rich beam cocktails, enabling experiments along the proton dripline.

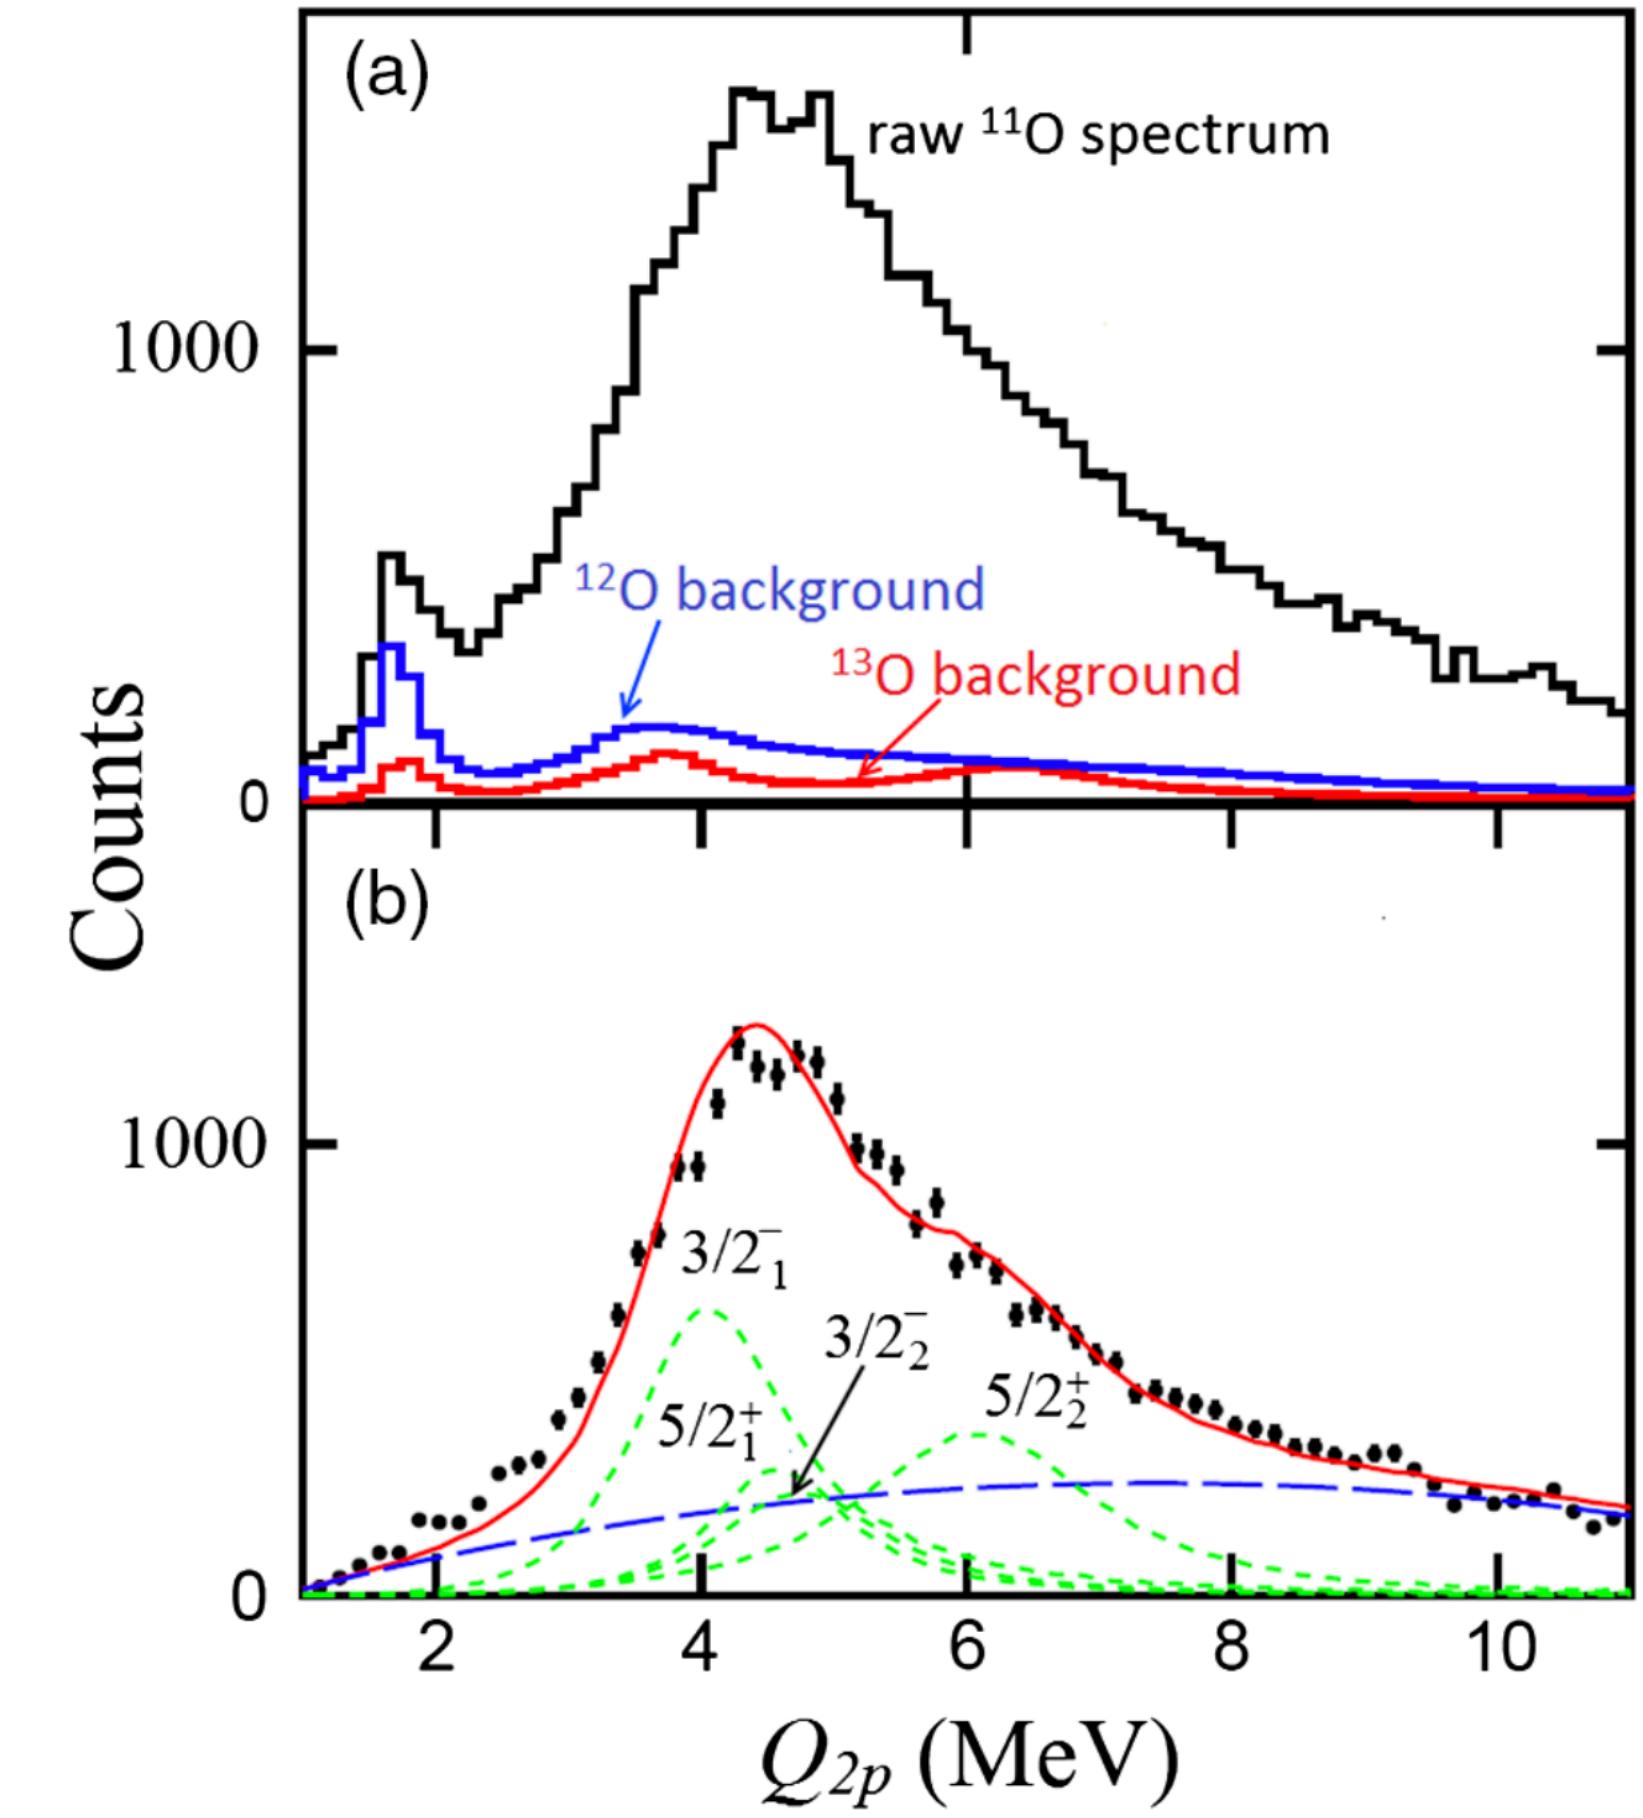

# First Observation of $^{11}\text{O}$

High Resolution Array (HiRA)

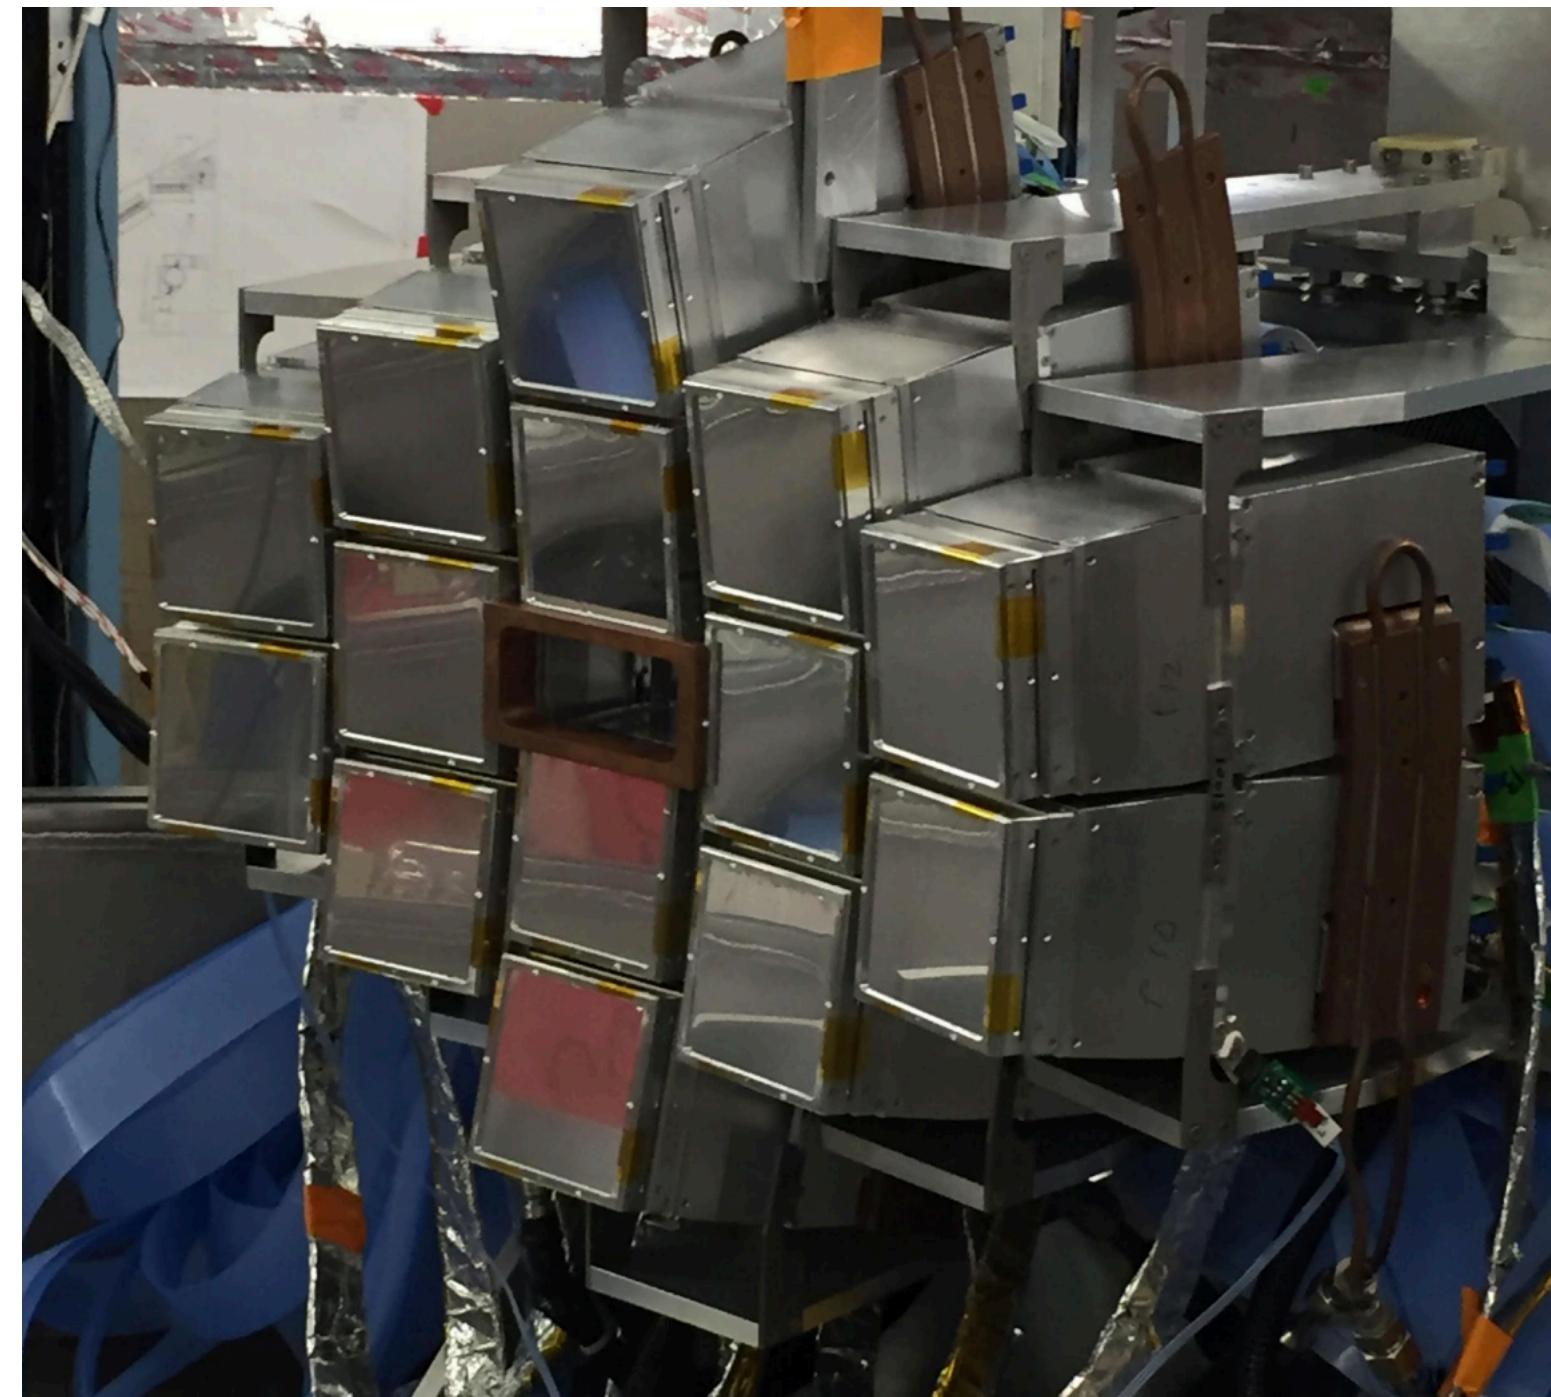

- $^{11}\text{O}$  was first observed by fragmenting a  $^{13}\text{O}$  secondary beam on a Be target, looking for  $^{9}\text{C}+2\text{p}$  events in HiRA.
- After A1900 secondary beam only had 10% of  $^{13}\text{O}$ .
- **After passing through RFFS 80% of beam consisted of  $^{13}\text{O}$ !**

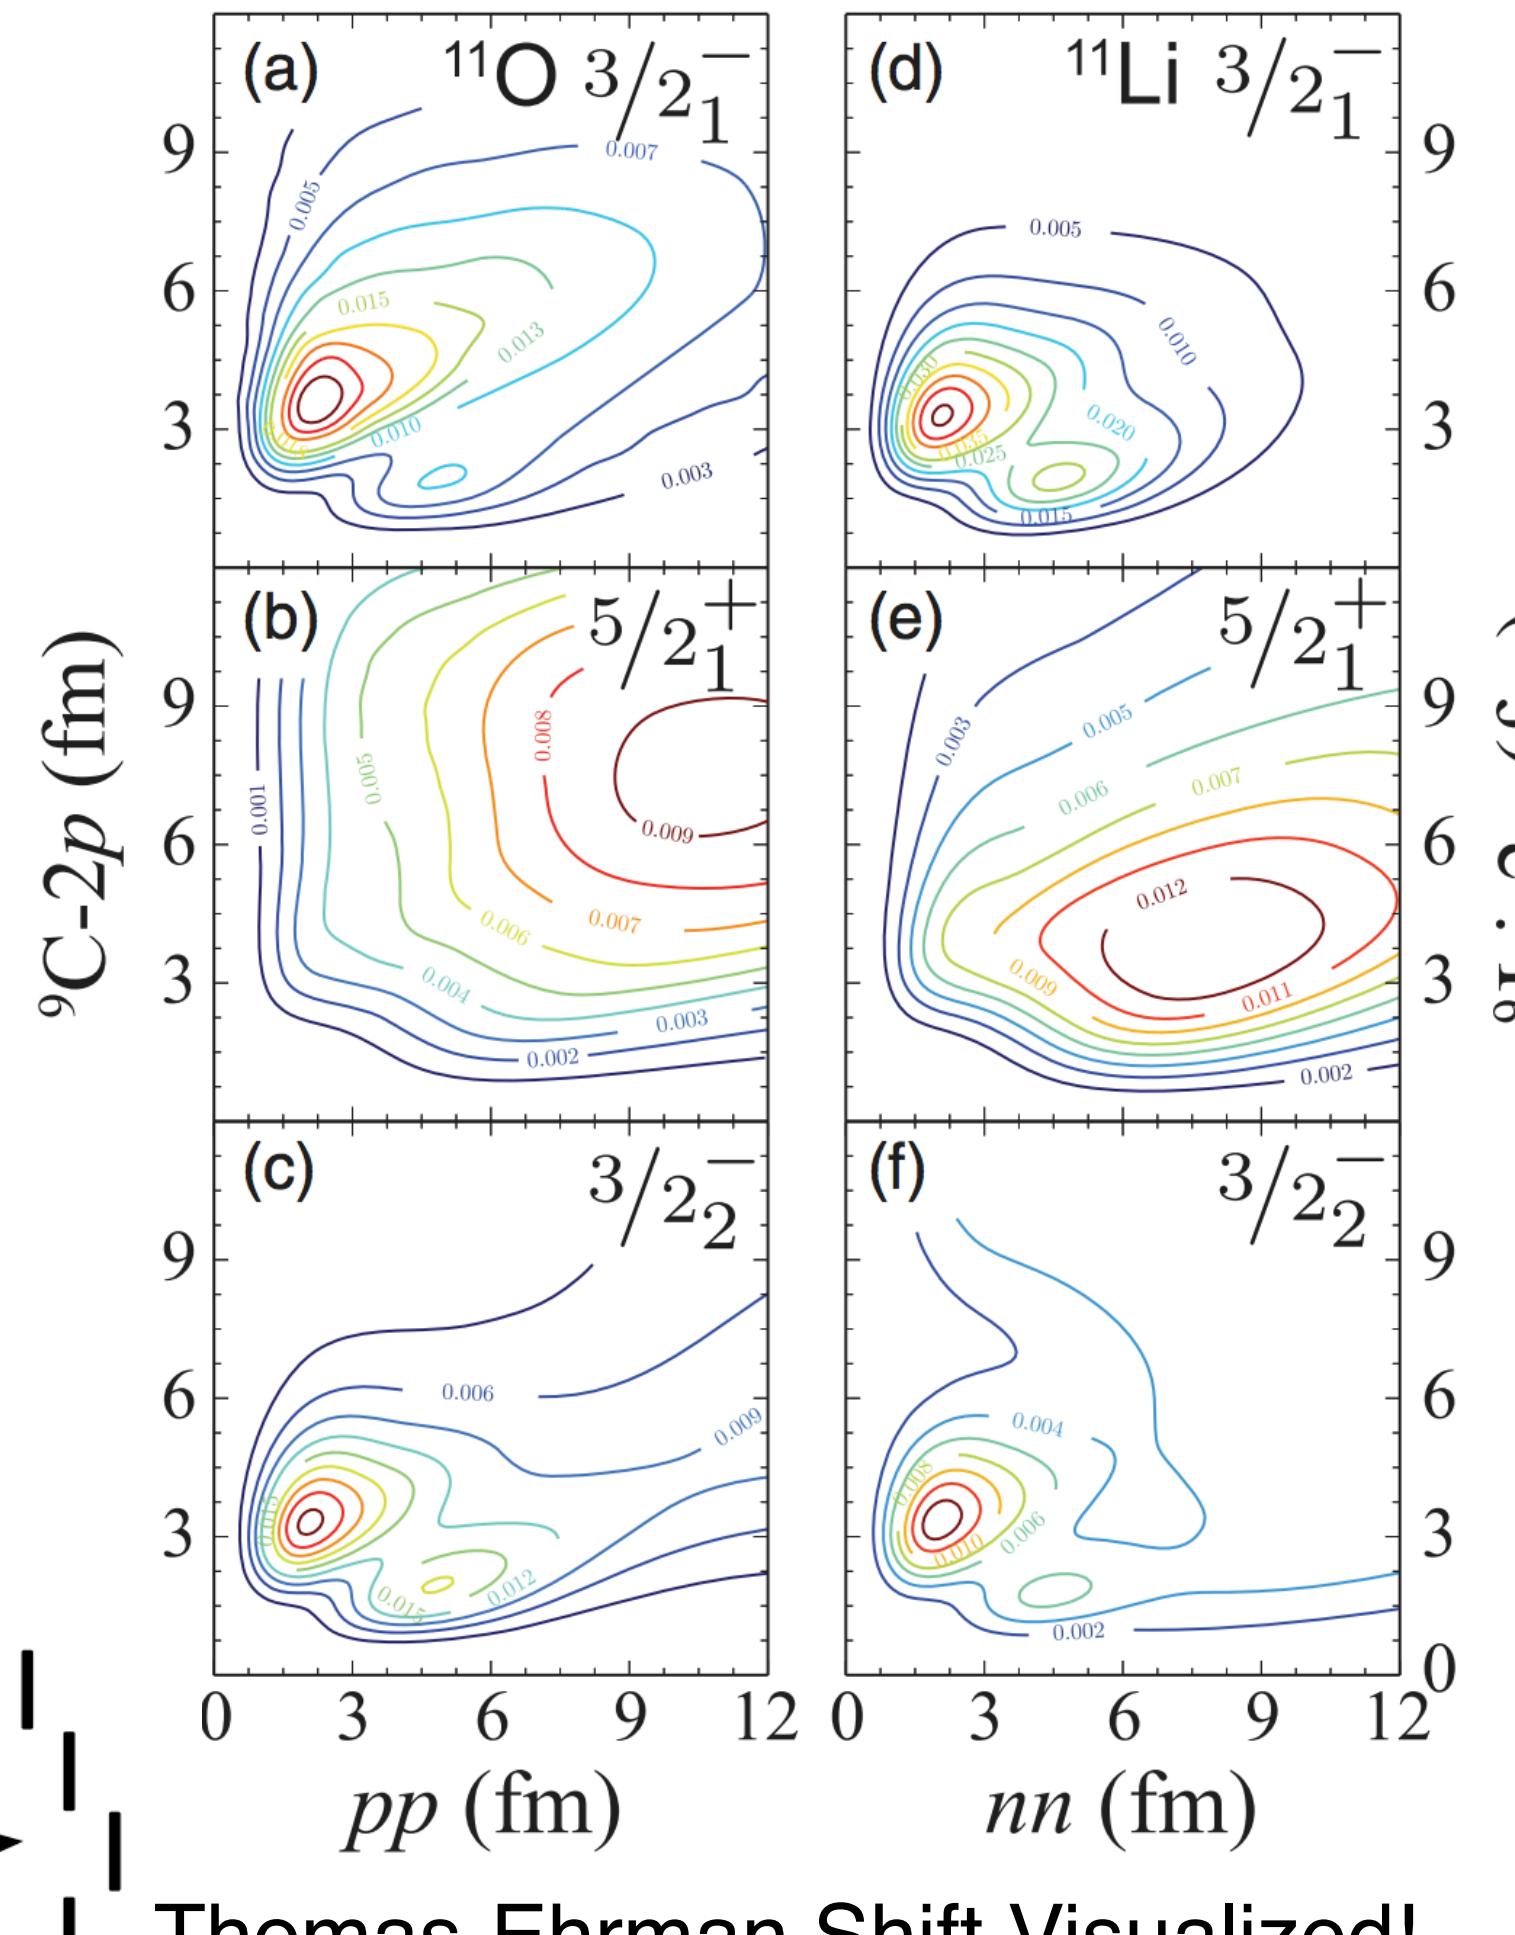

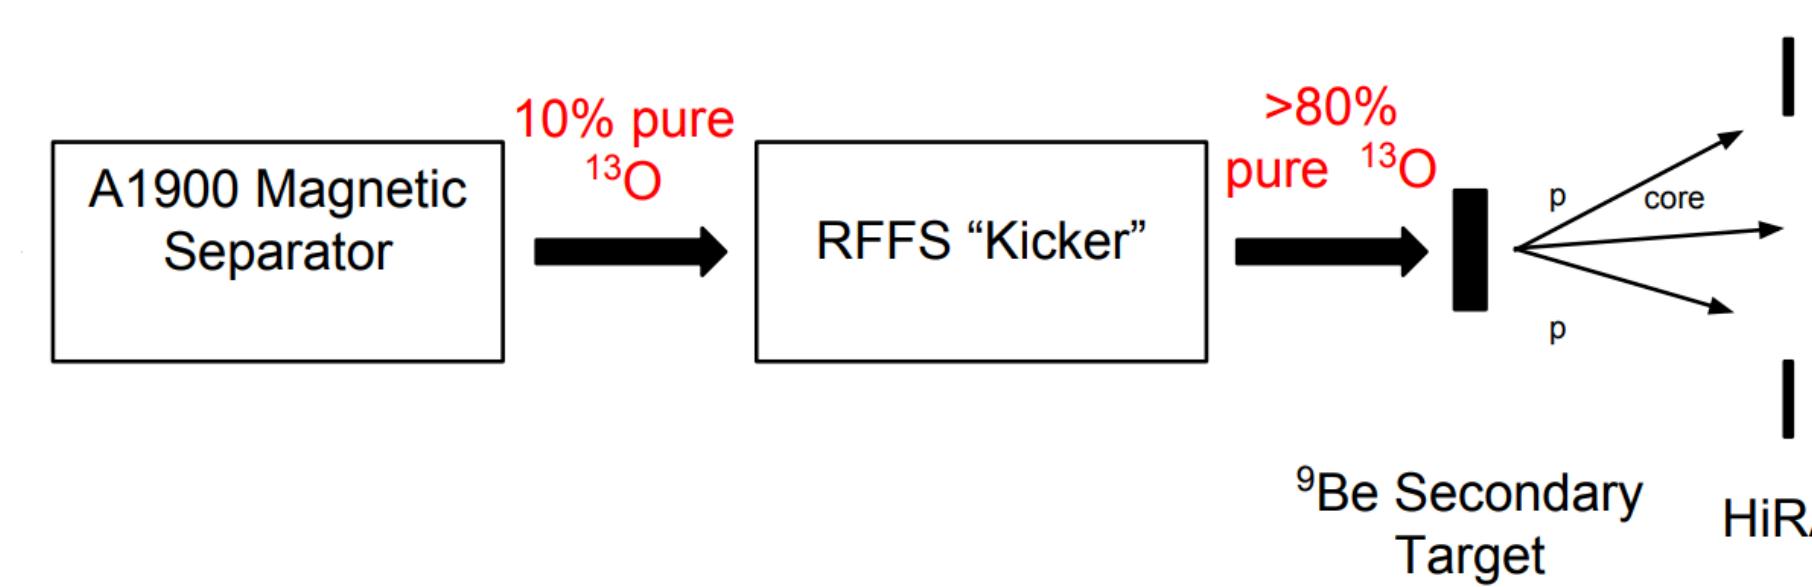

T.B. Webb et al., Phys. Rev. Lett. **122** (2019)

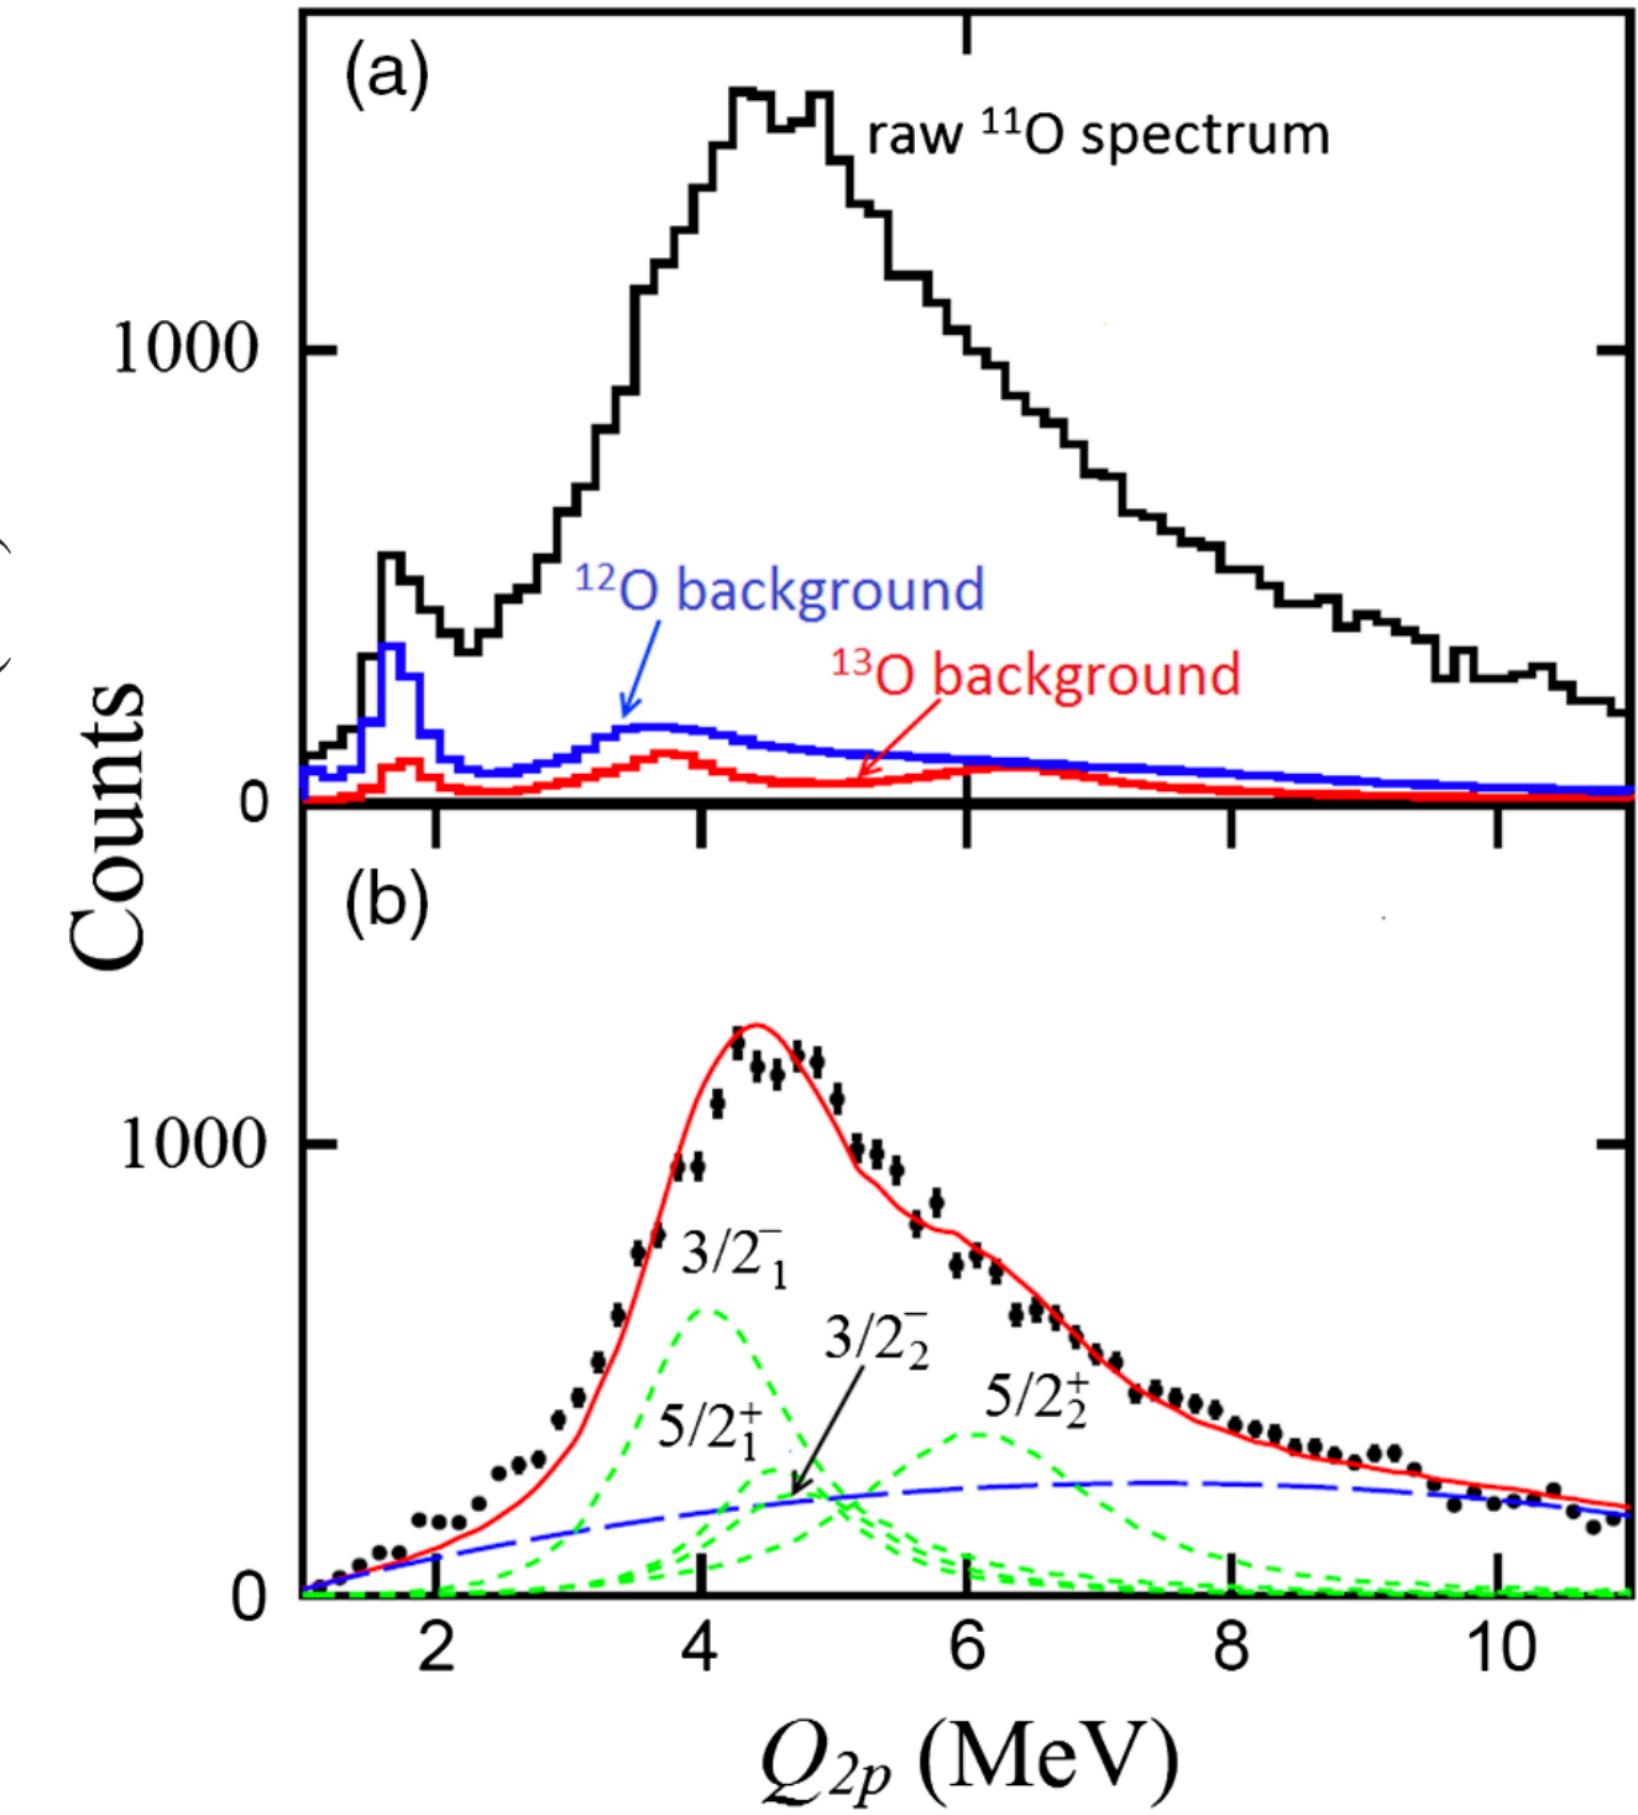

# First Observation of $^{11}\text{O}$

High Resolution Array (HiRA)

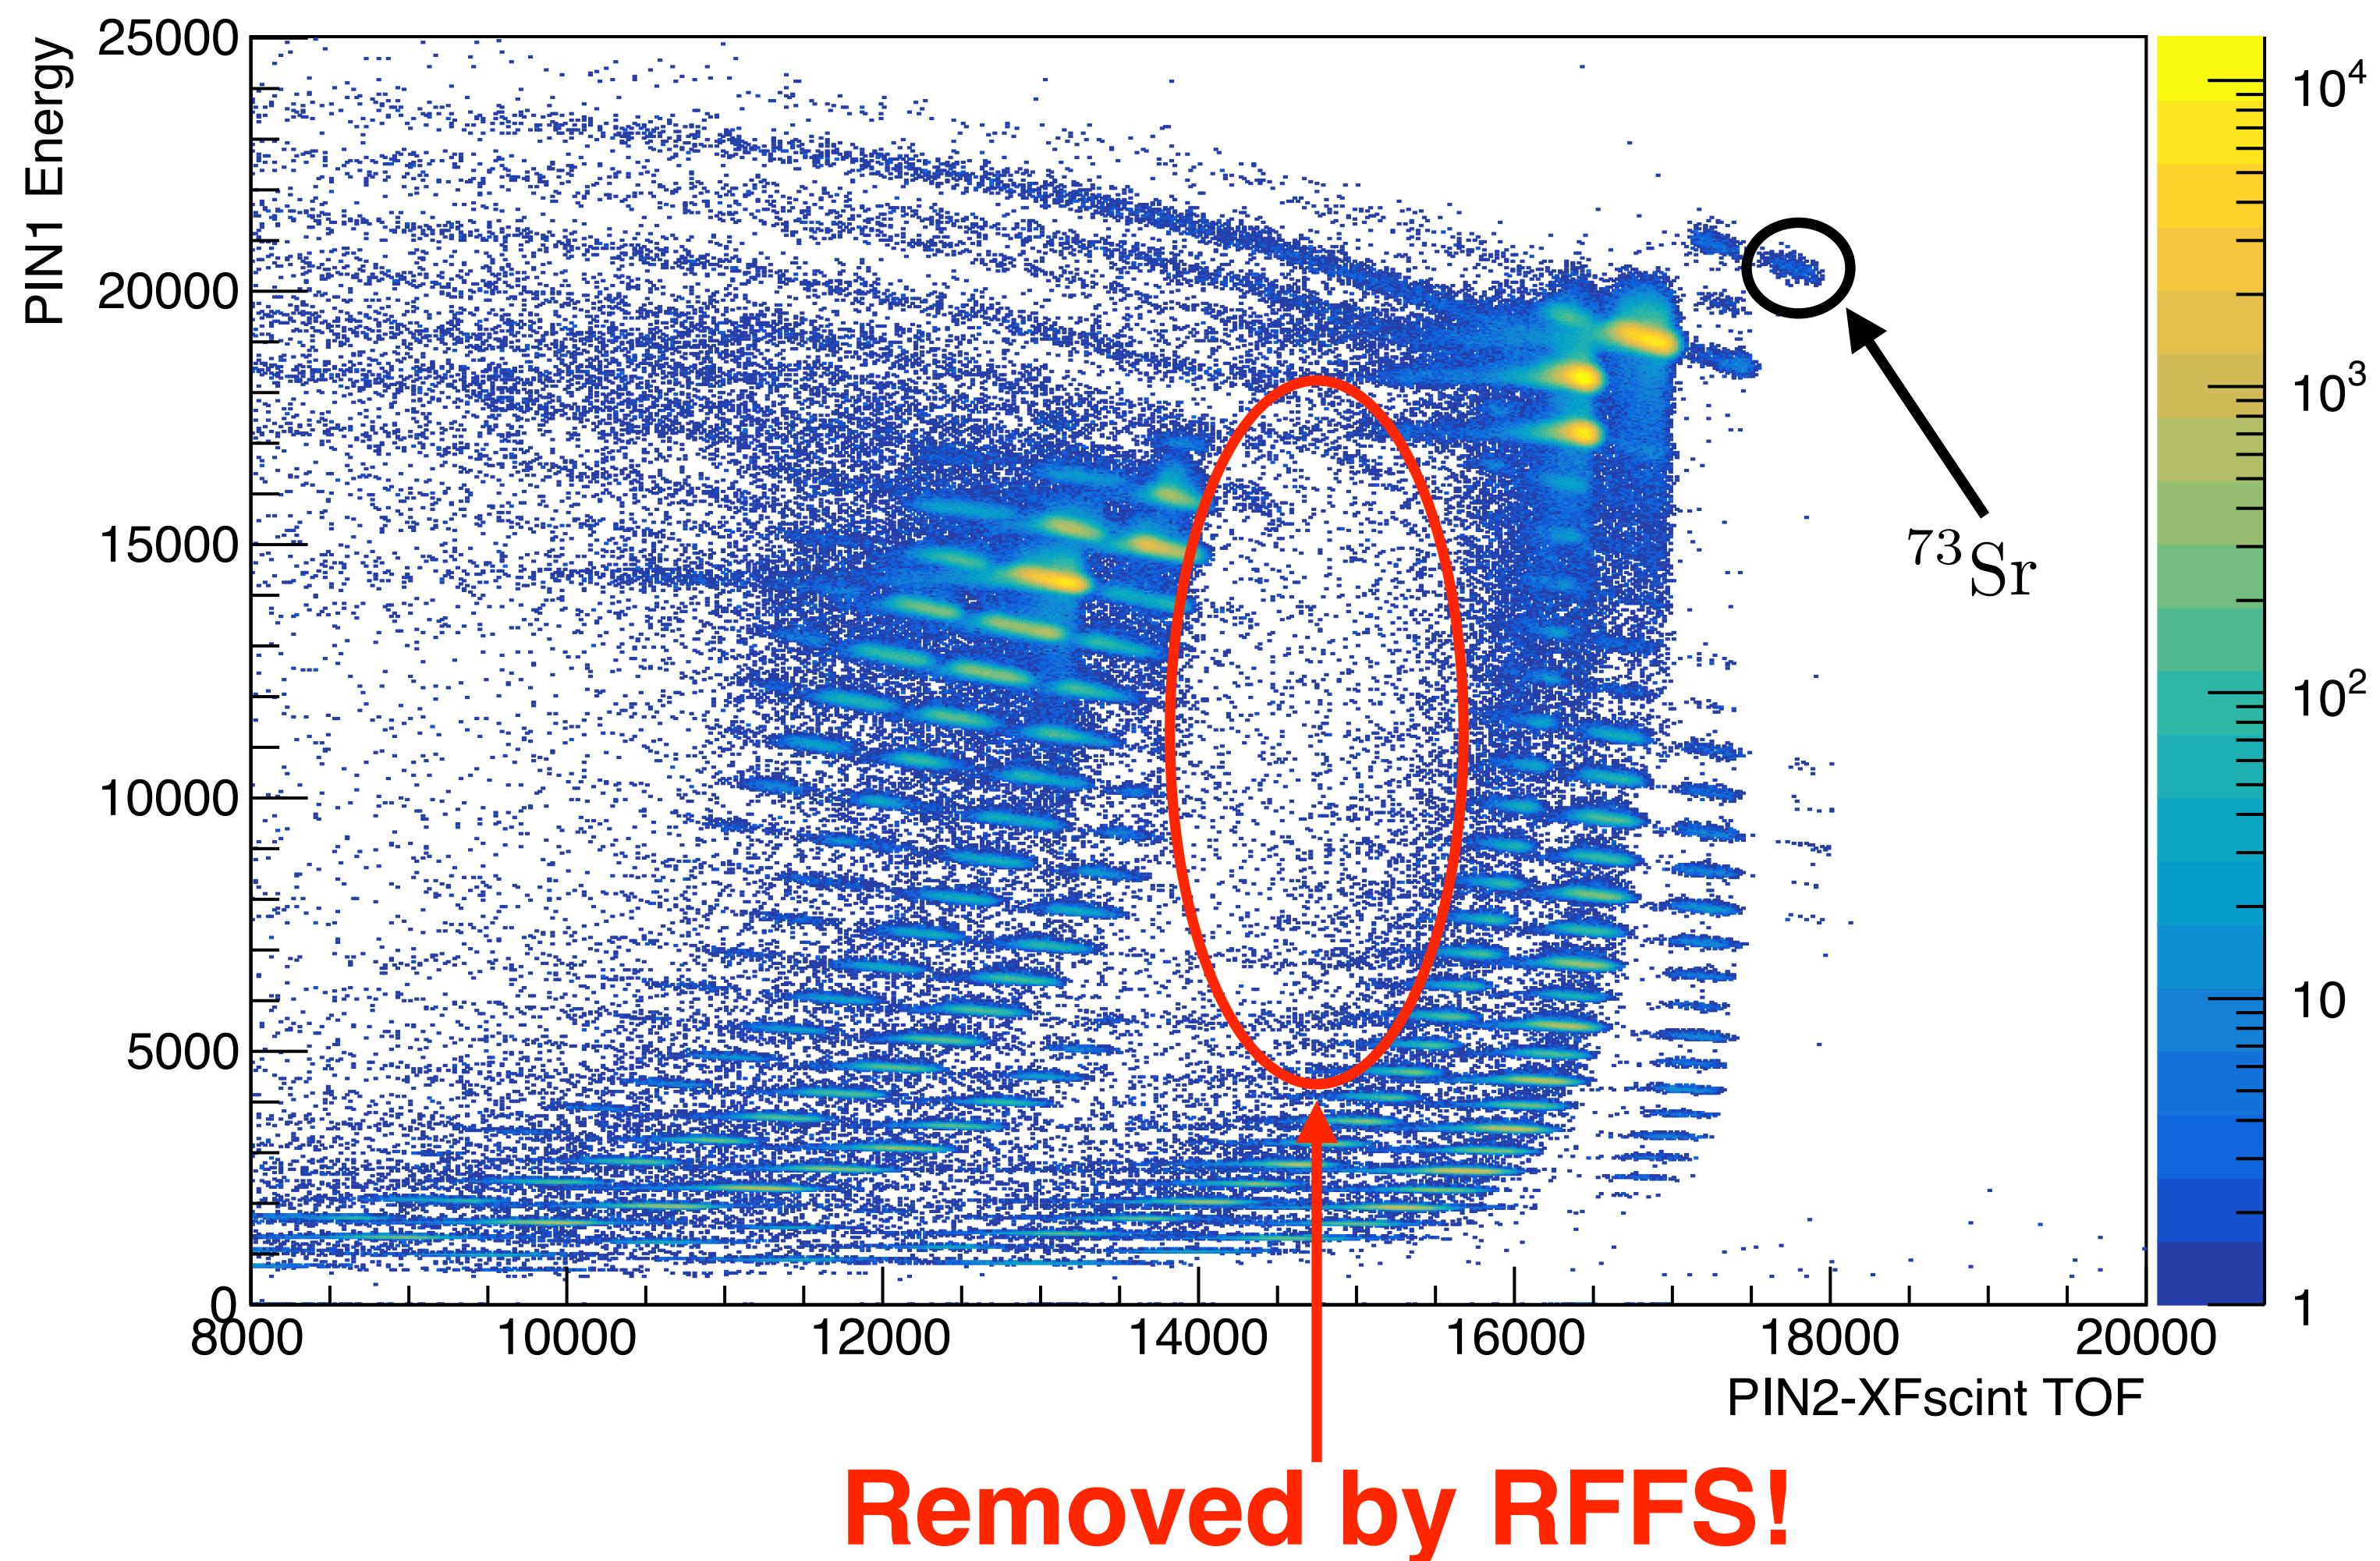

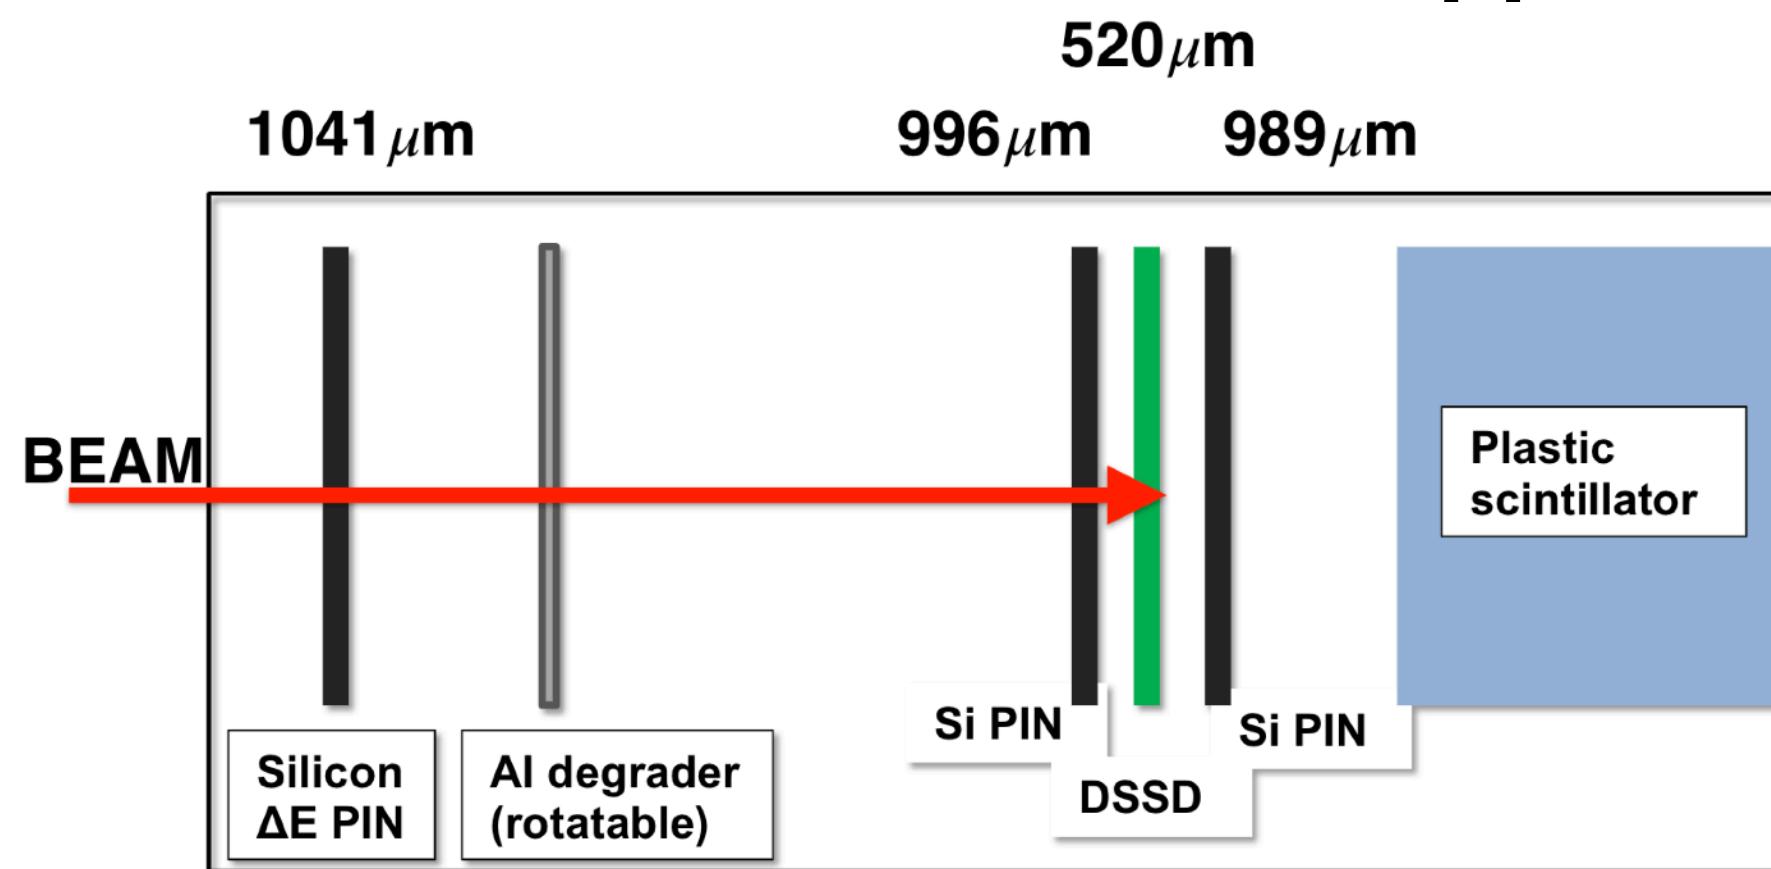

Thomas-Ehrman Shift Visualized!

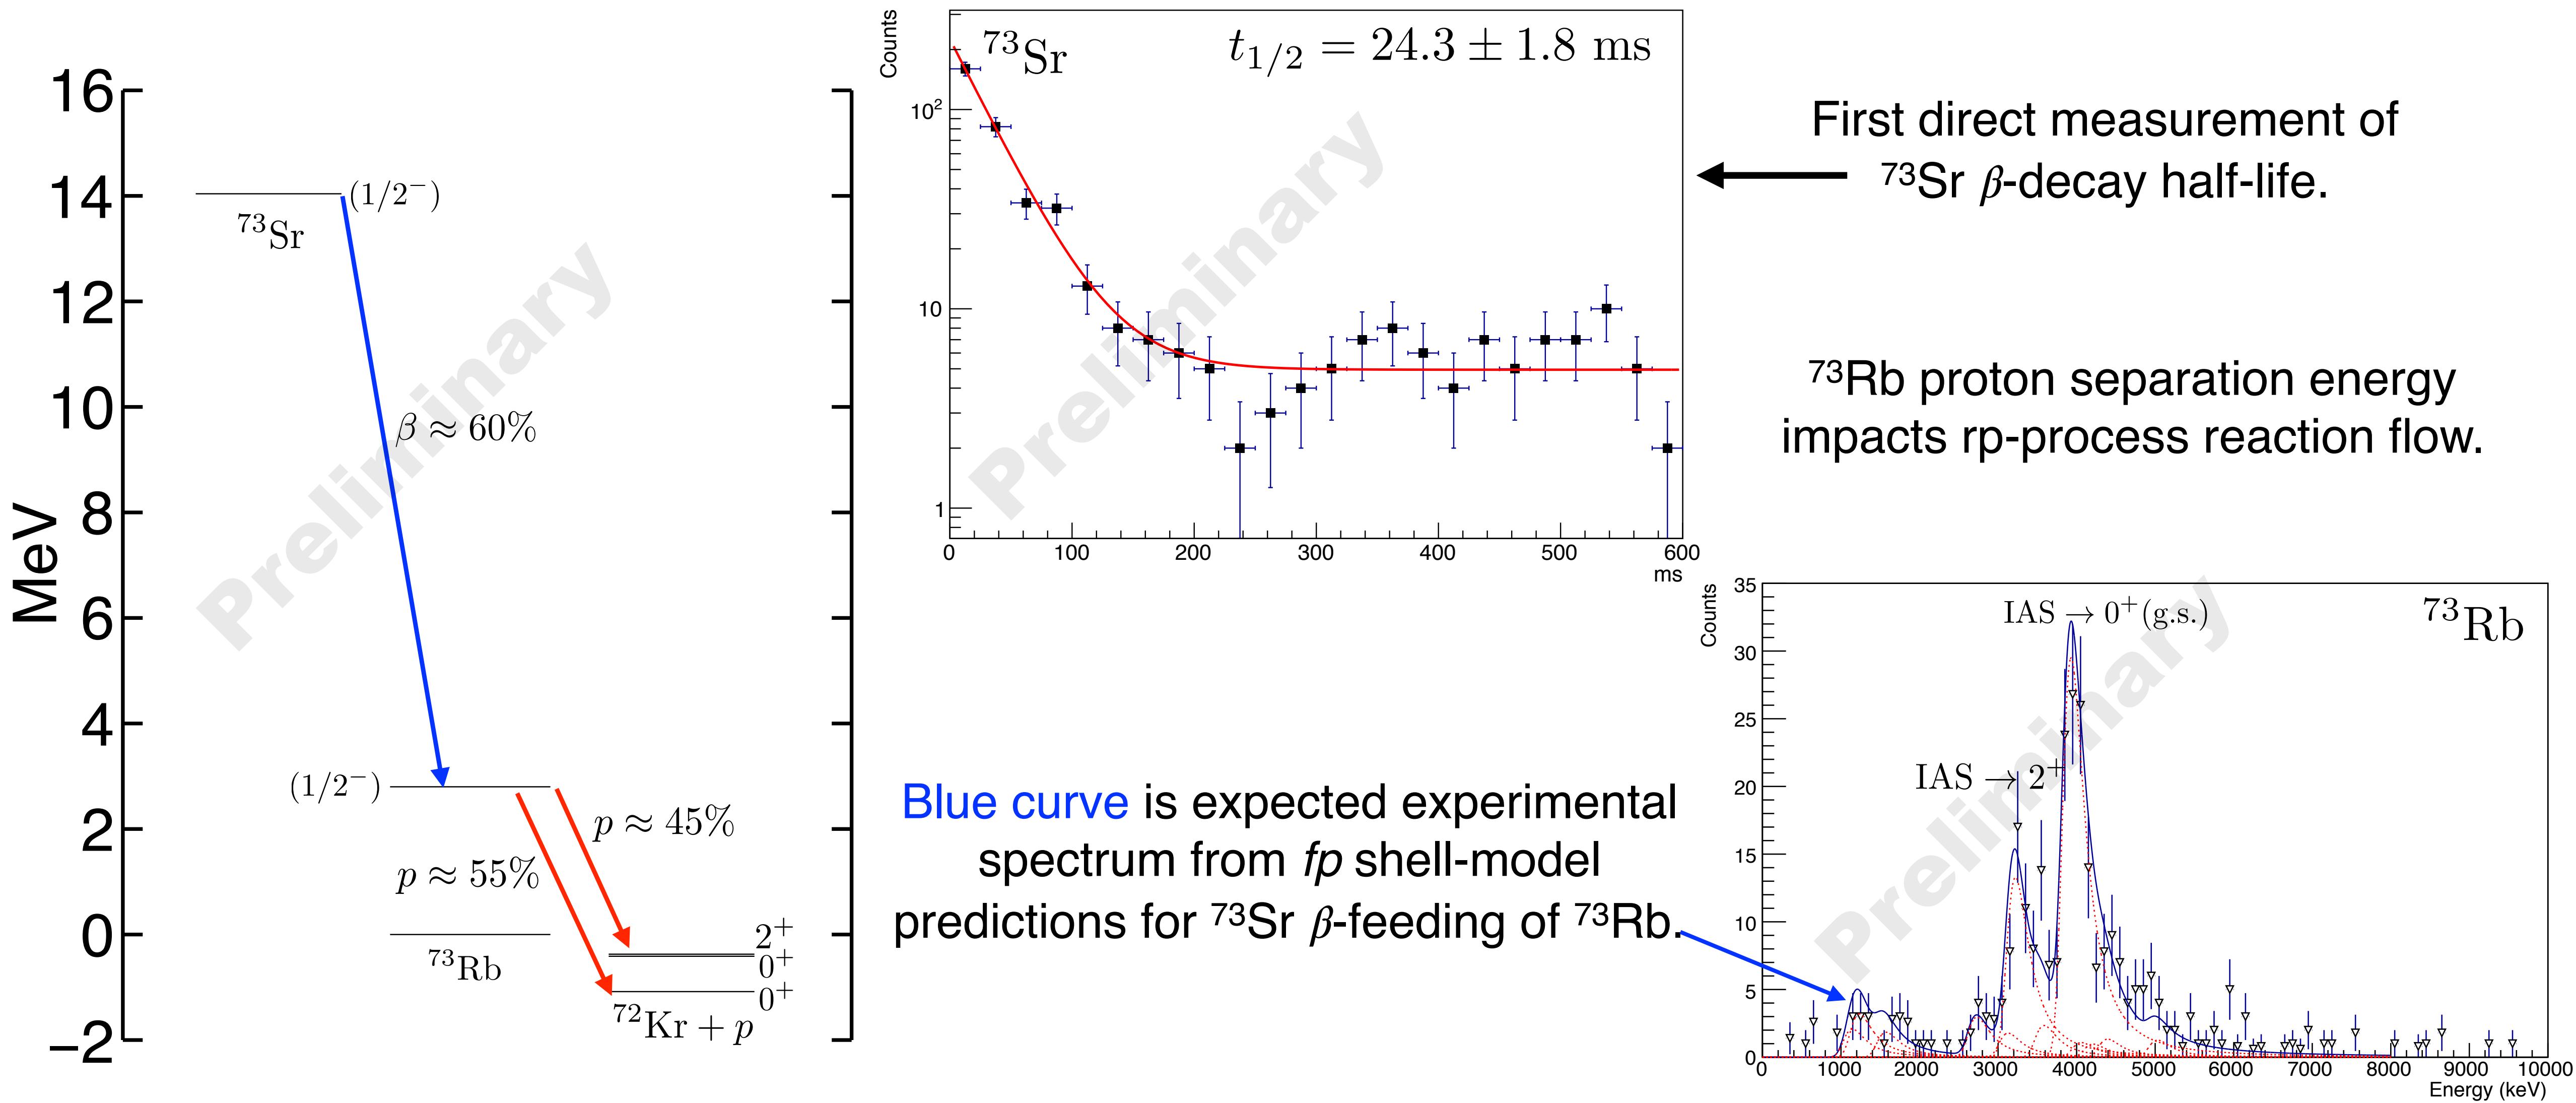

T.B. Webb et al., Phys. Rev. Lett. **122** (2019)

# $^{73}\text{Sr}$ $\beta$ -delayed proton emission

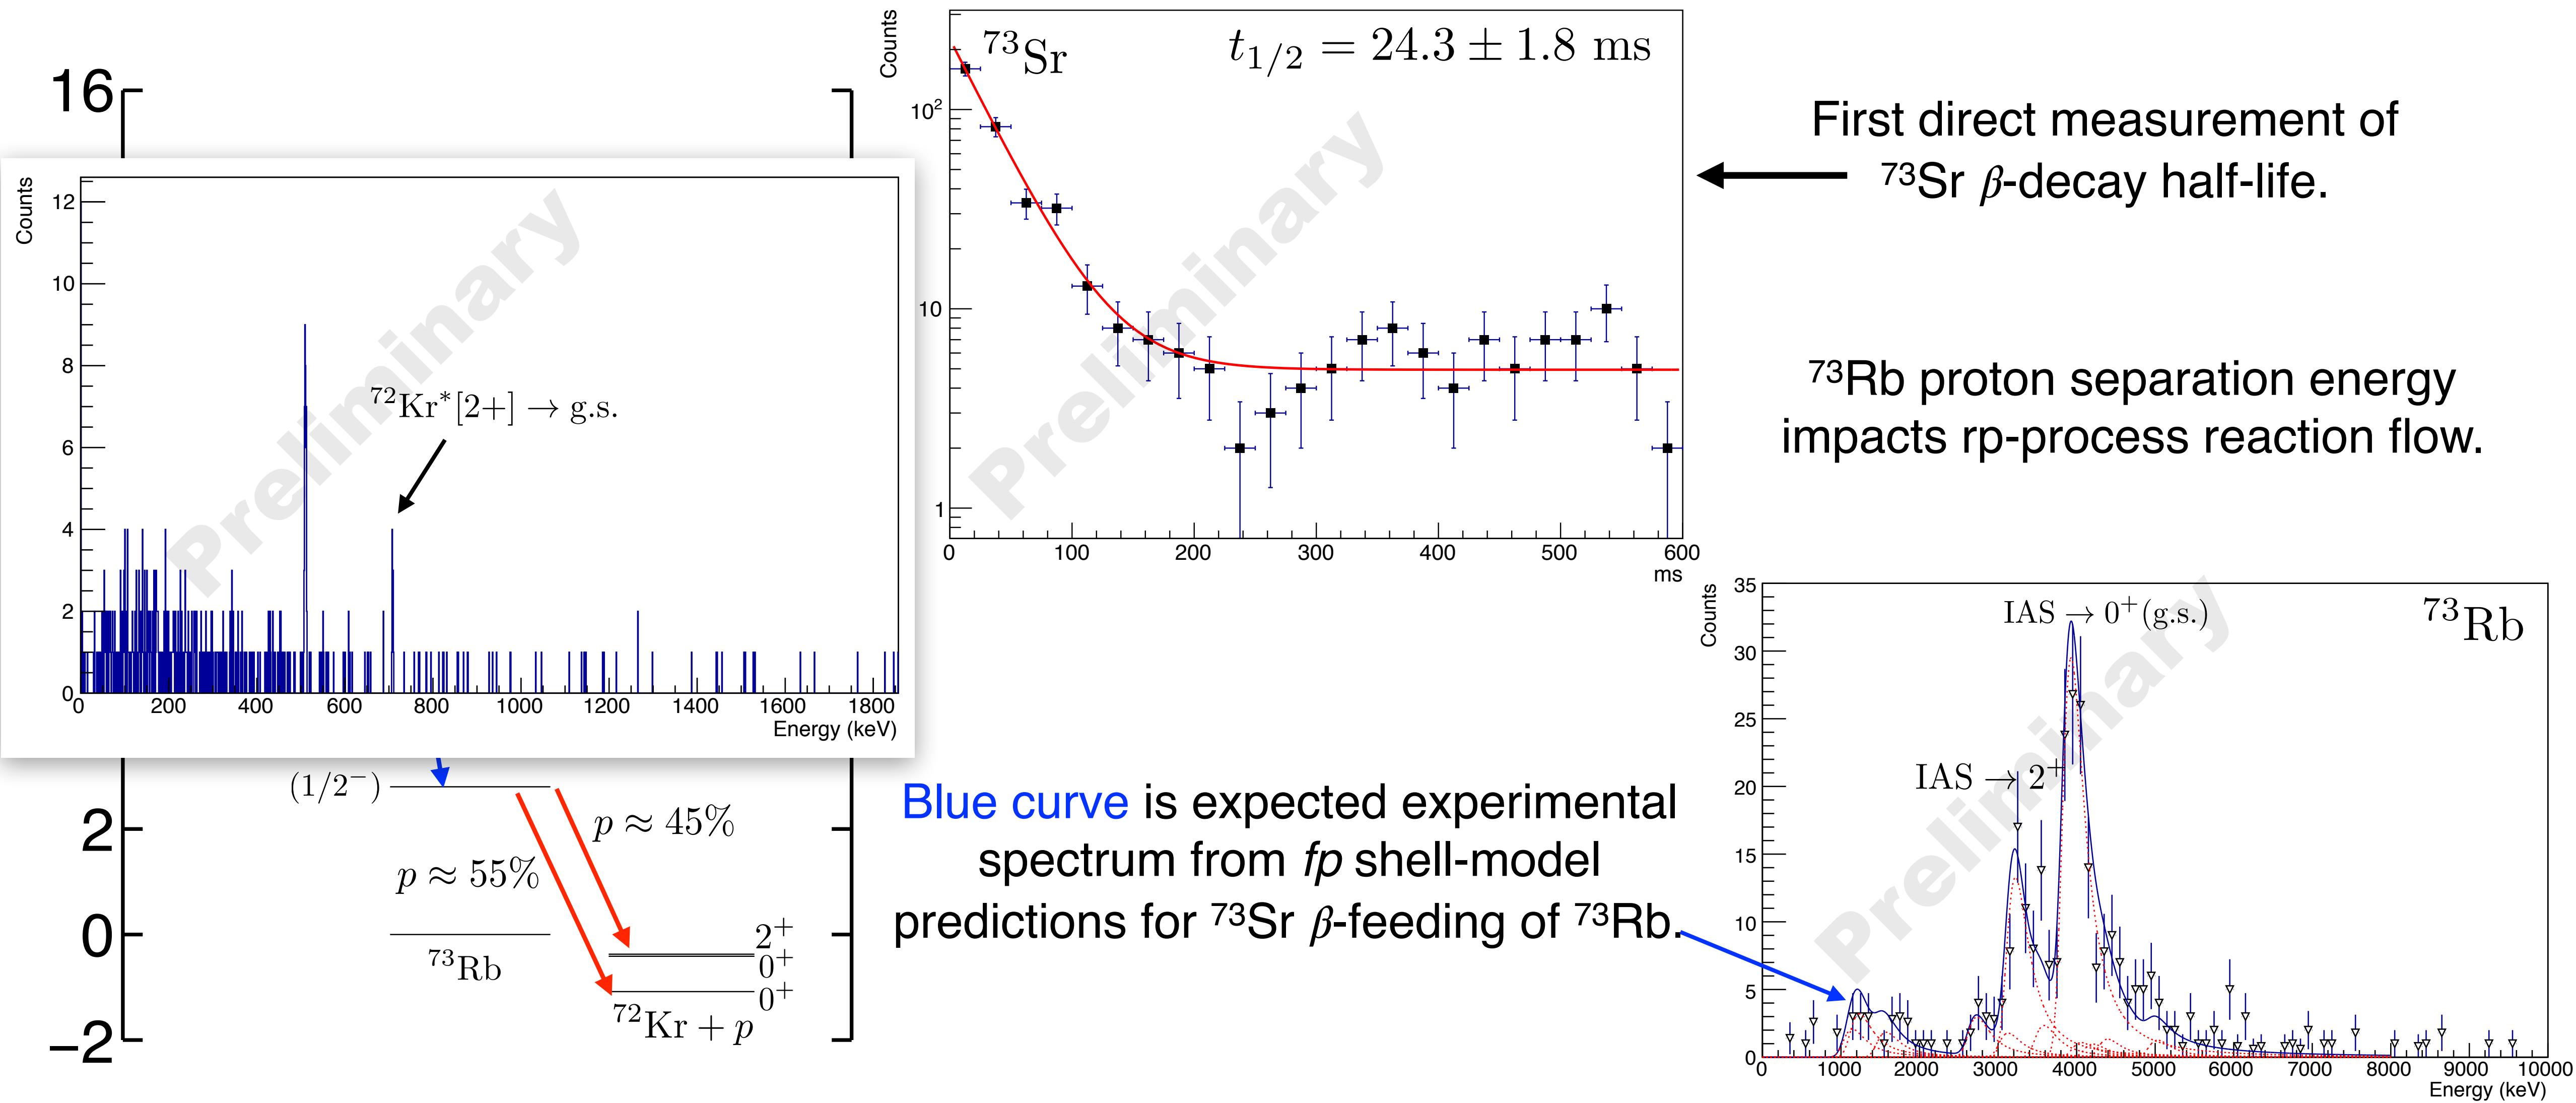

- Current RFFS has already been used to study nuclei that would have been unfeasible due to beam contaminates.
- Measured properties of  $^{73}\text{Rb}$ , by watching beta-decay of  $^{73}\text{Sr}$  secondary beam implanted into a DSSD. **Beam was purified by a factor of 4500 down to 10 pps!**

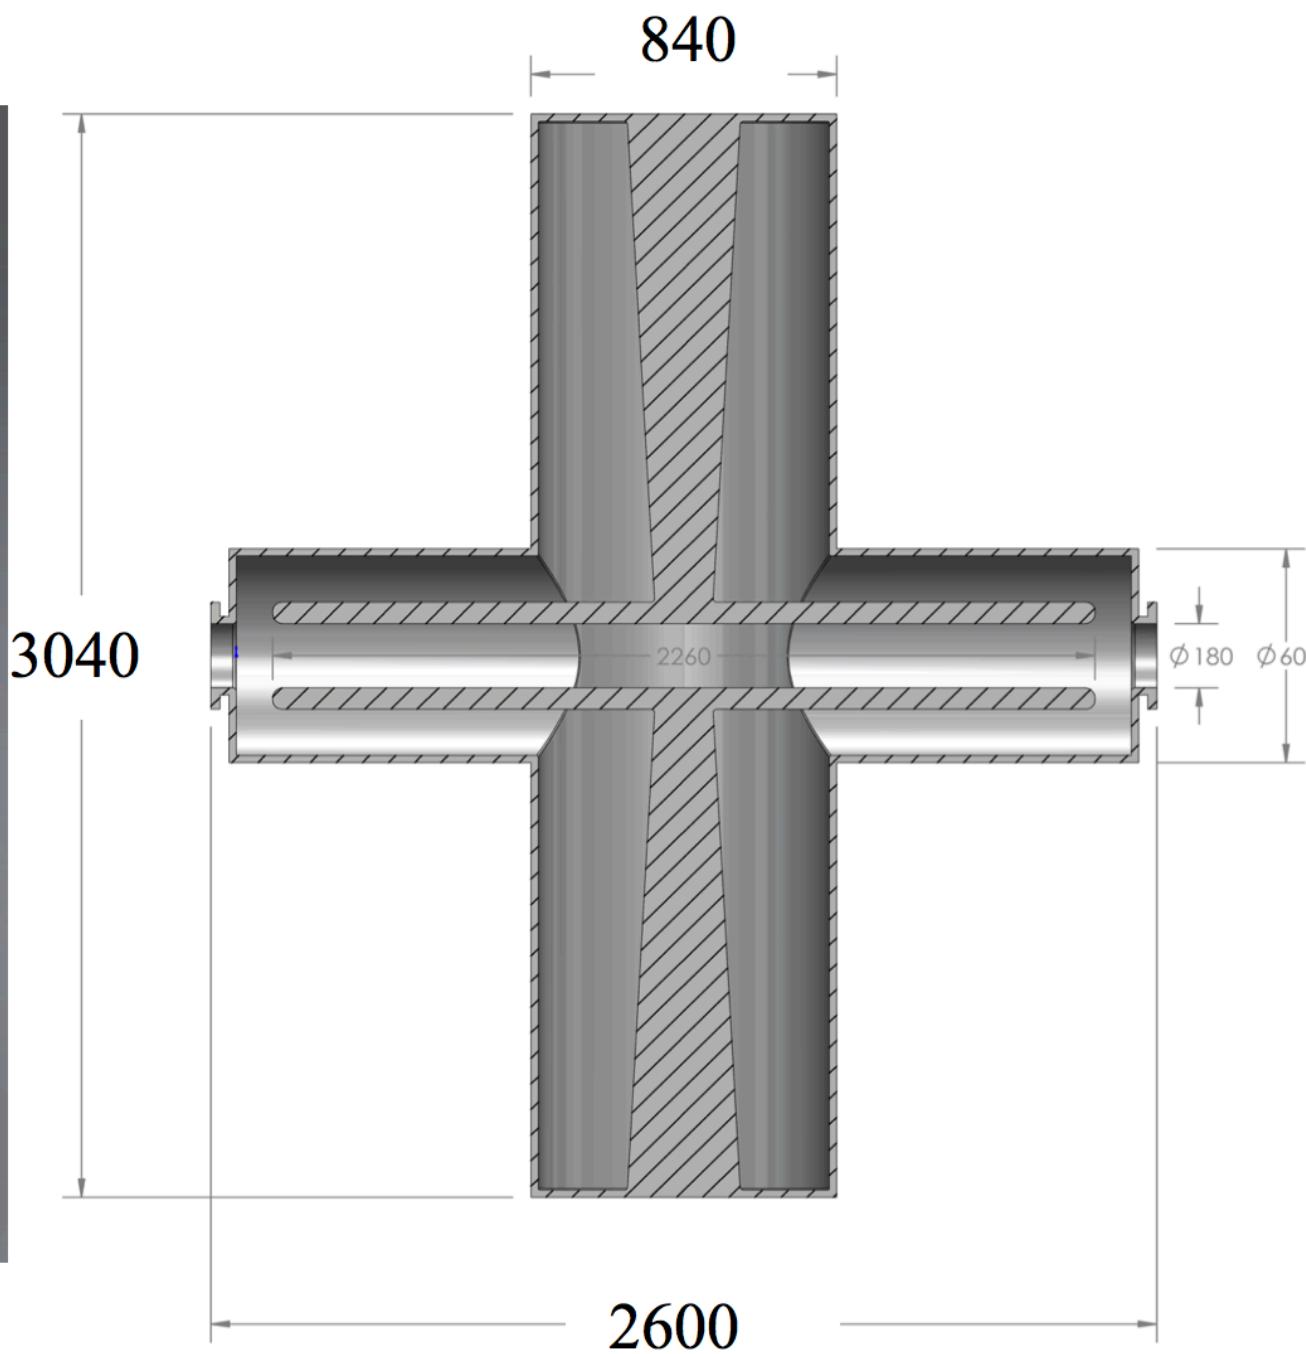

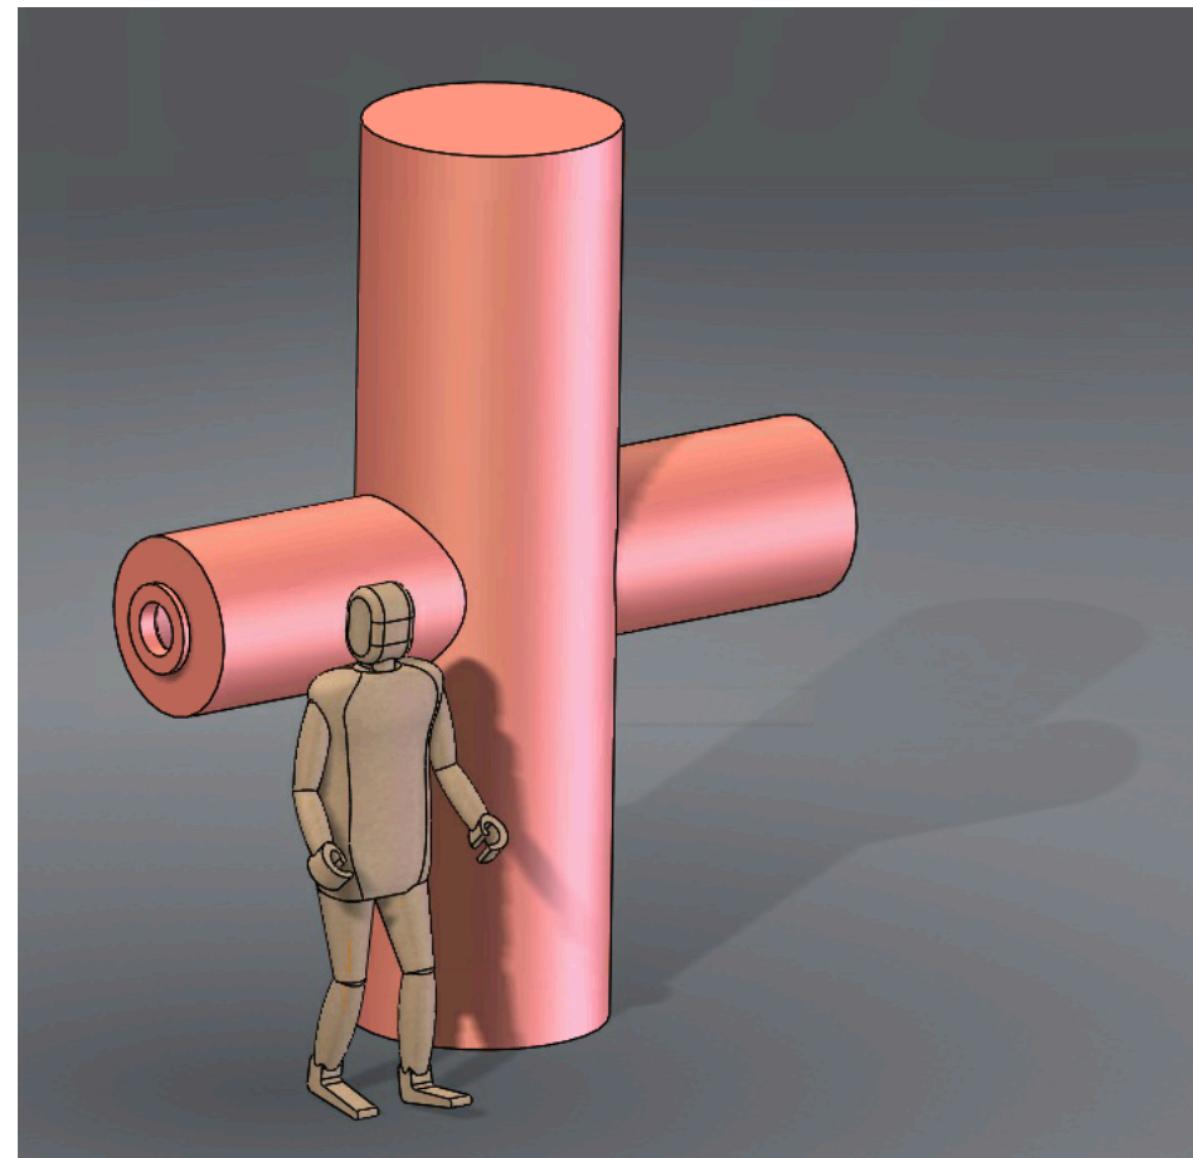

# $^{73}\text{Sr}$ $\beta$ -delayed proton emission

# $^{73}\text{Sr}$ $\beta$ -delayed proton emission

# RFSS at FRIB

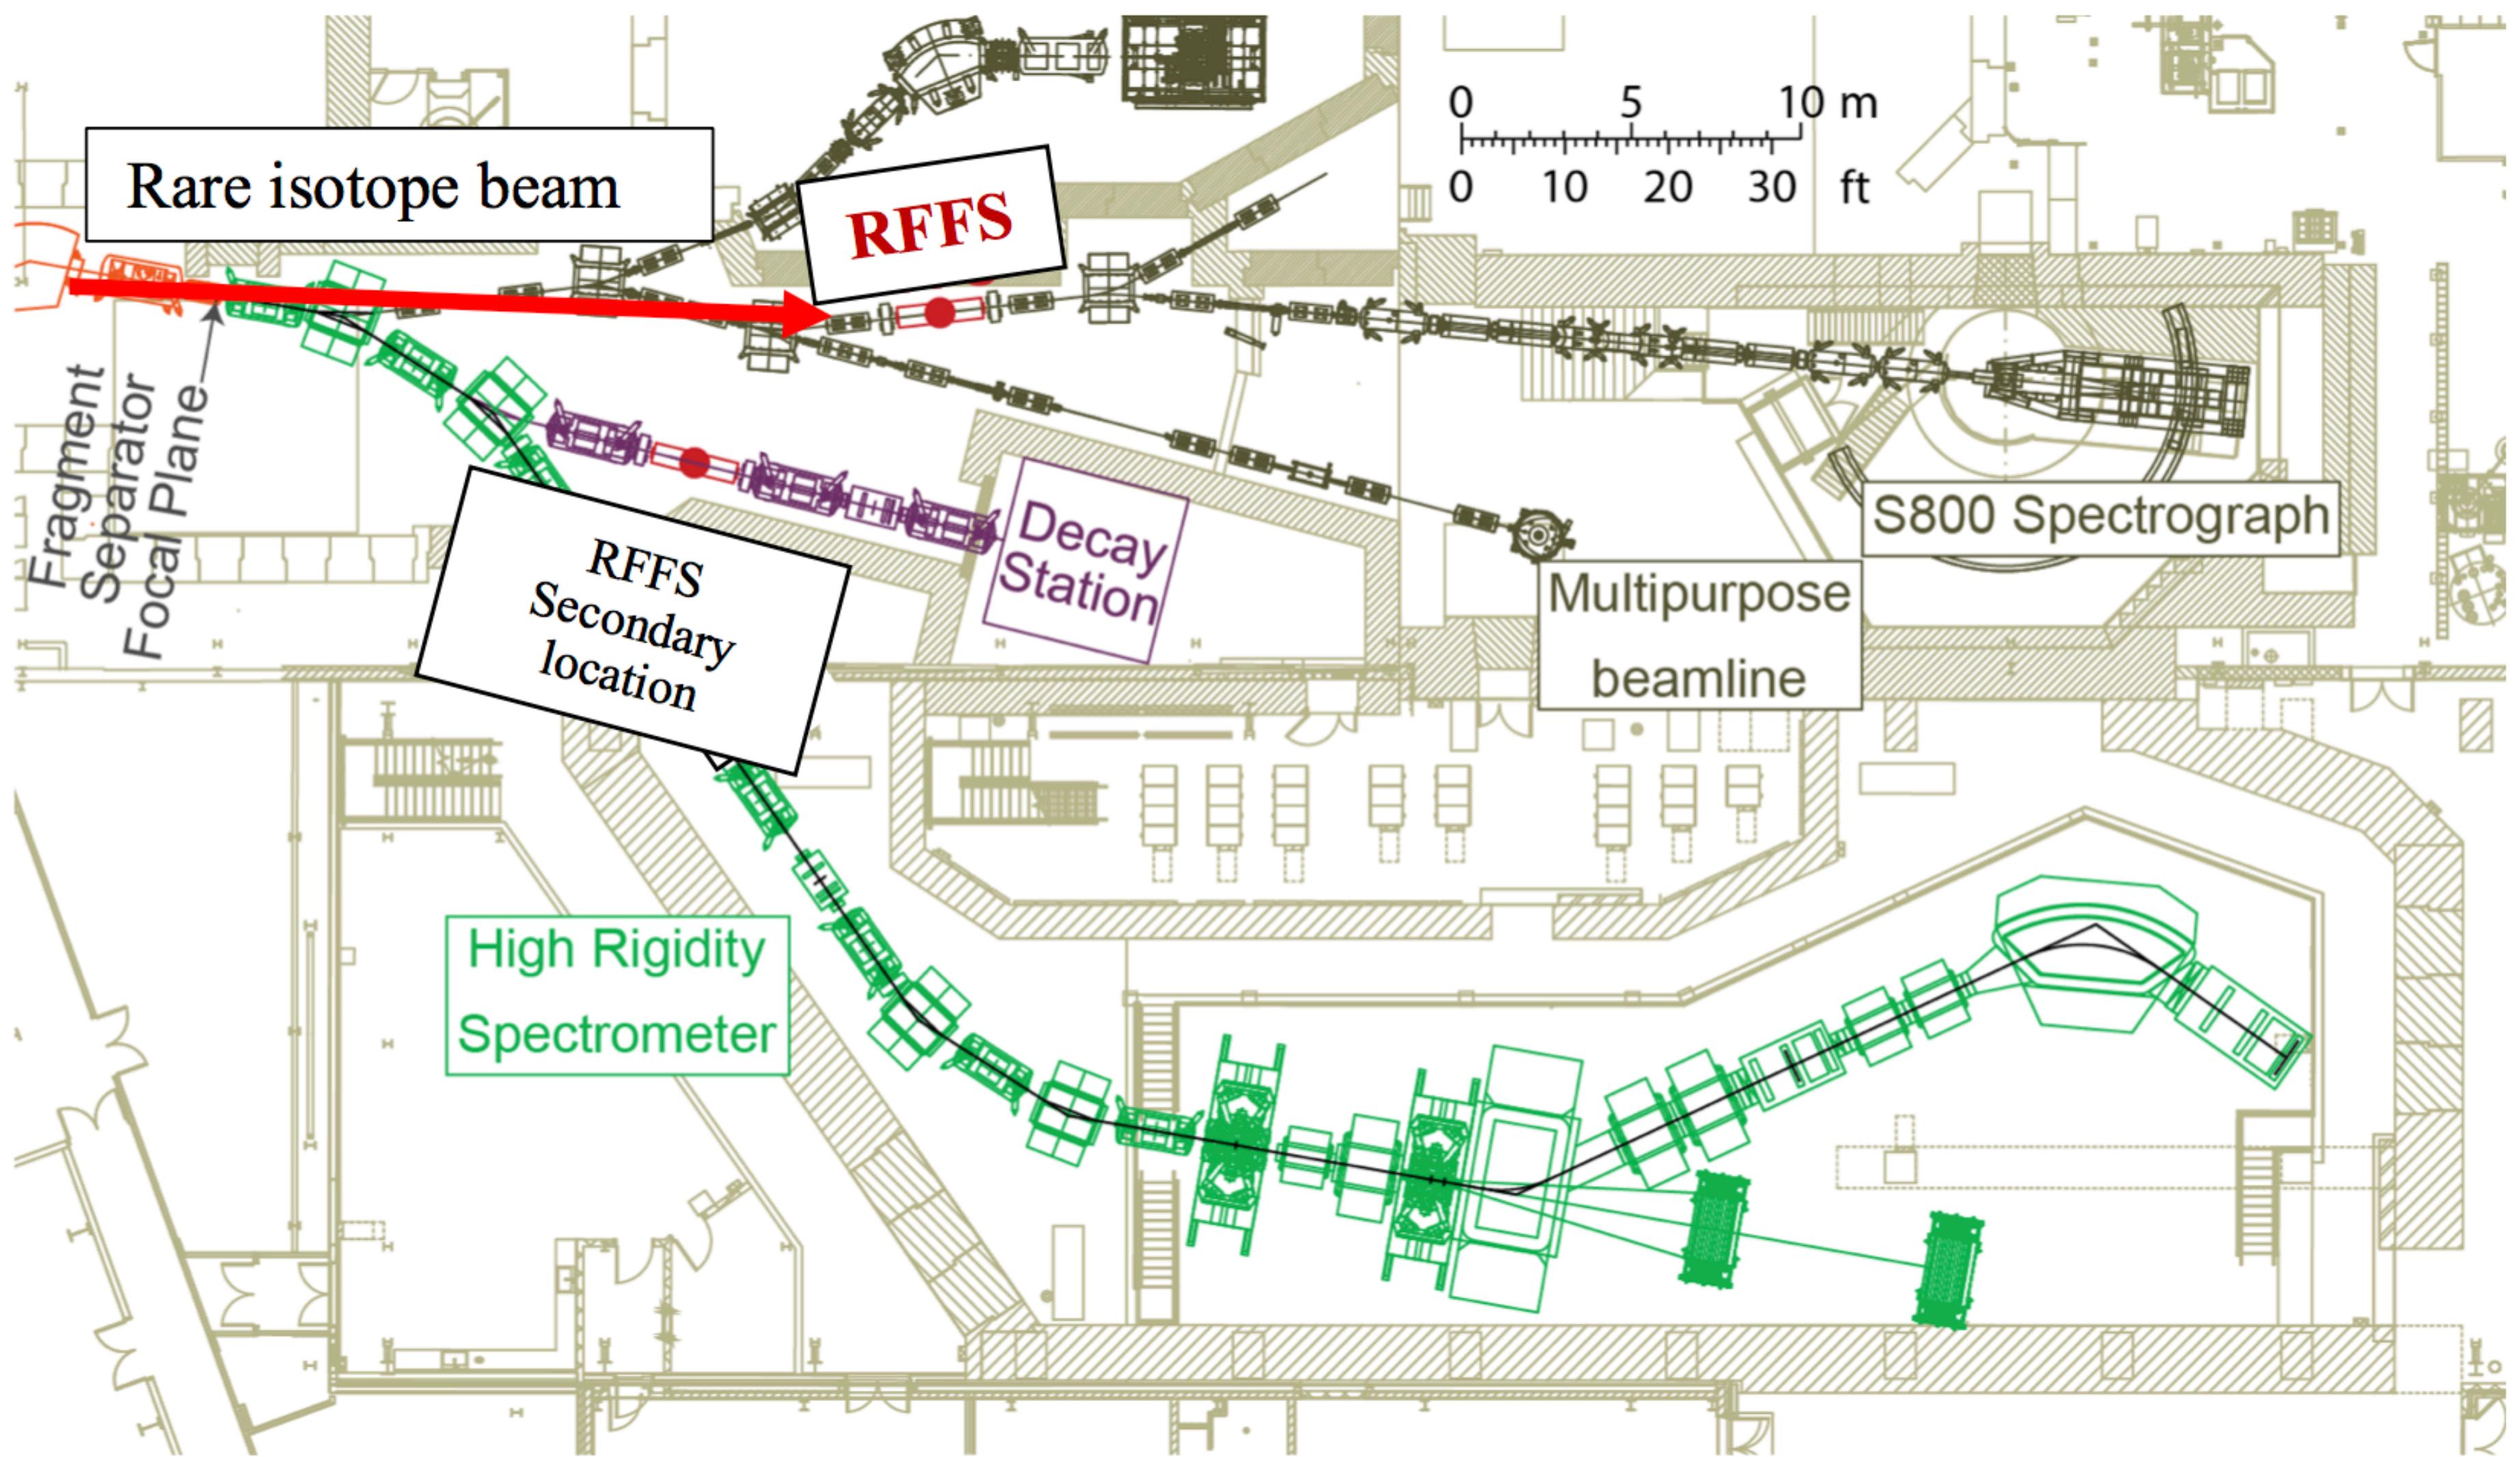

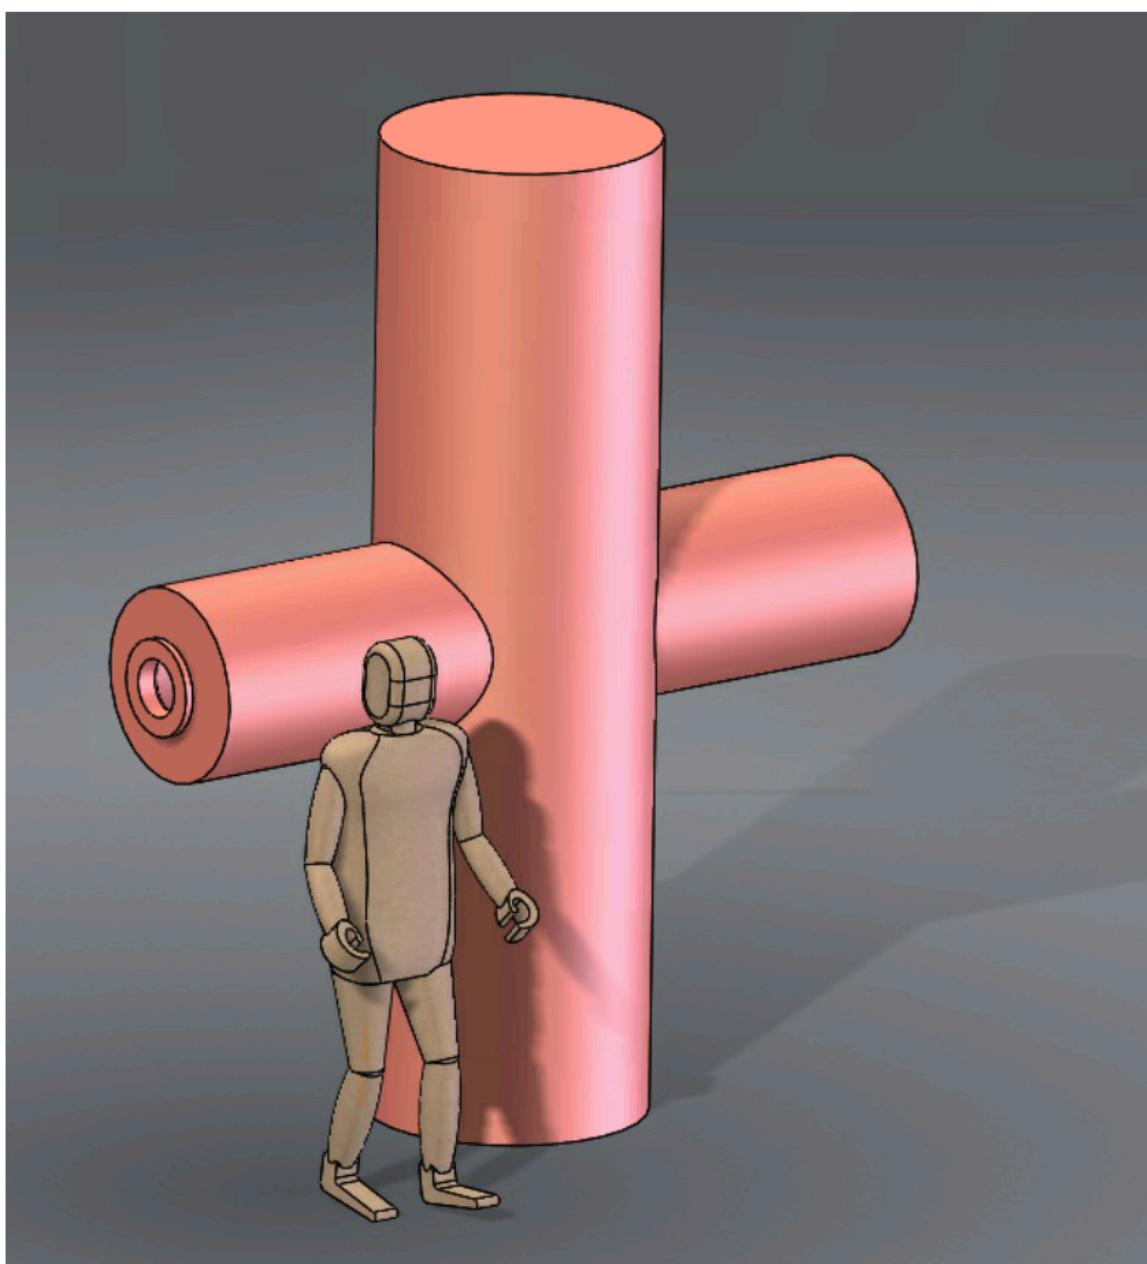

Cavity design has been investigated with E&M simulations performed by Alexander Plastun

<b>Electrodes (plates)</b>	Width	26	cm
	Length	226	cm
	Gap	18	cm
	Field gradient	17	kV/cm
	Voltage	$\pm 153$	kV
	Peak surface field	46	kV/cm
	$\int_{-\infty}^{\infty} E_y(z) dz$	4	MV
<b>Coaxial line of QWR</b>	Inner diameter of the tank	80	cm
	Outer diameter of the stem	16.31	cm
	Height	138	cm
<b>Chamber inner dimensions</b>	Length	246	cm
	Diameter	56	cm
<b>RF parameters</b>	Frequency	20.125	MHz
	RF power consumption	$2 \times 21$	kW
	Quality factor	12,900	
<b>Beam kick at the exit</b>	Positional	$\pm 1.3$	Cm
	Angular	$\pm 8.6$	mrad

- Operating at 80 MHz of FRIB would result in “wrap around” of certain isotopes.
- Subharmonic bunching of 20.125 MHz will be implemented at FRIB upon funded construction of RFFS.
  - Larger gap to have large momentum acceptance of RIB’s.
  - Large gap requires larger resonators.

# RFSS at FRIB

Daniel E.M. Hoff – APS April Meeting – 04/15/2019

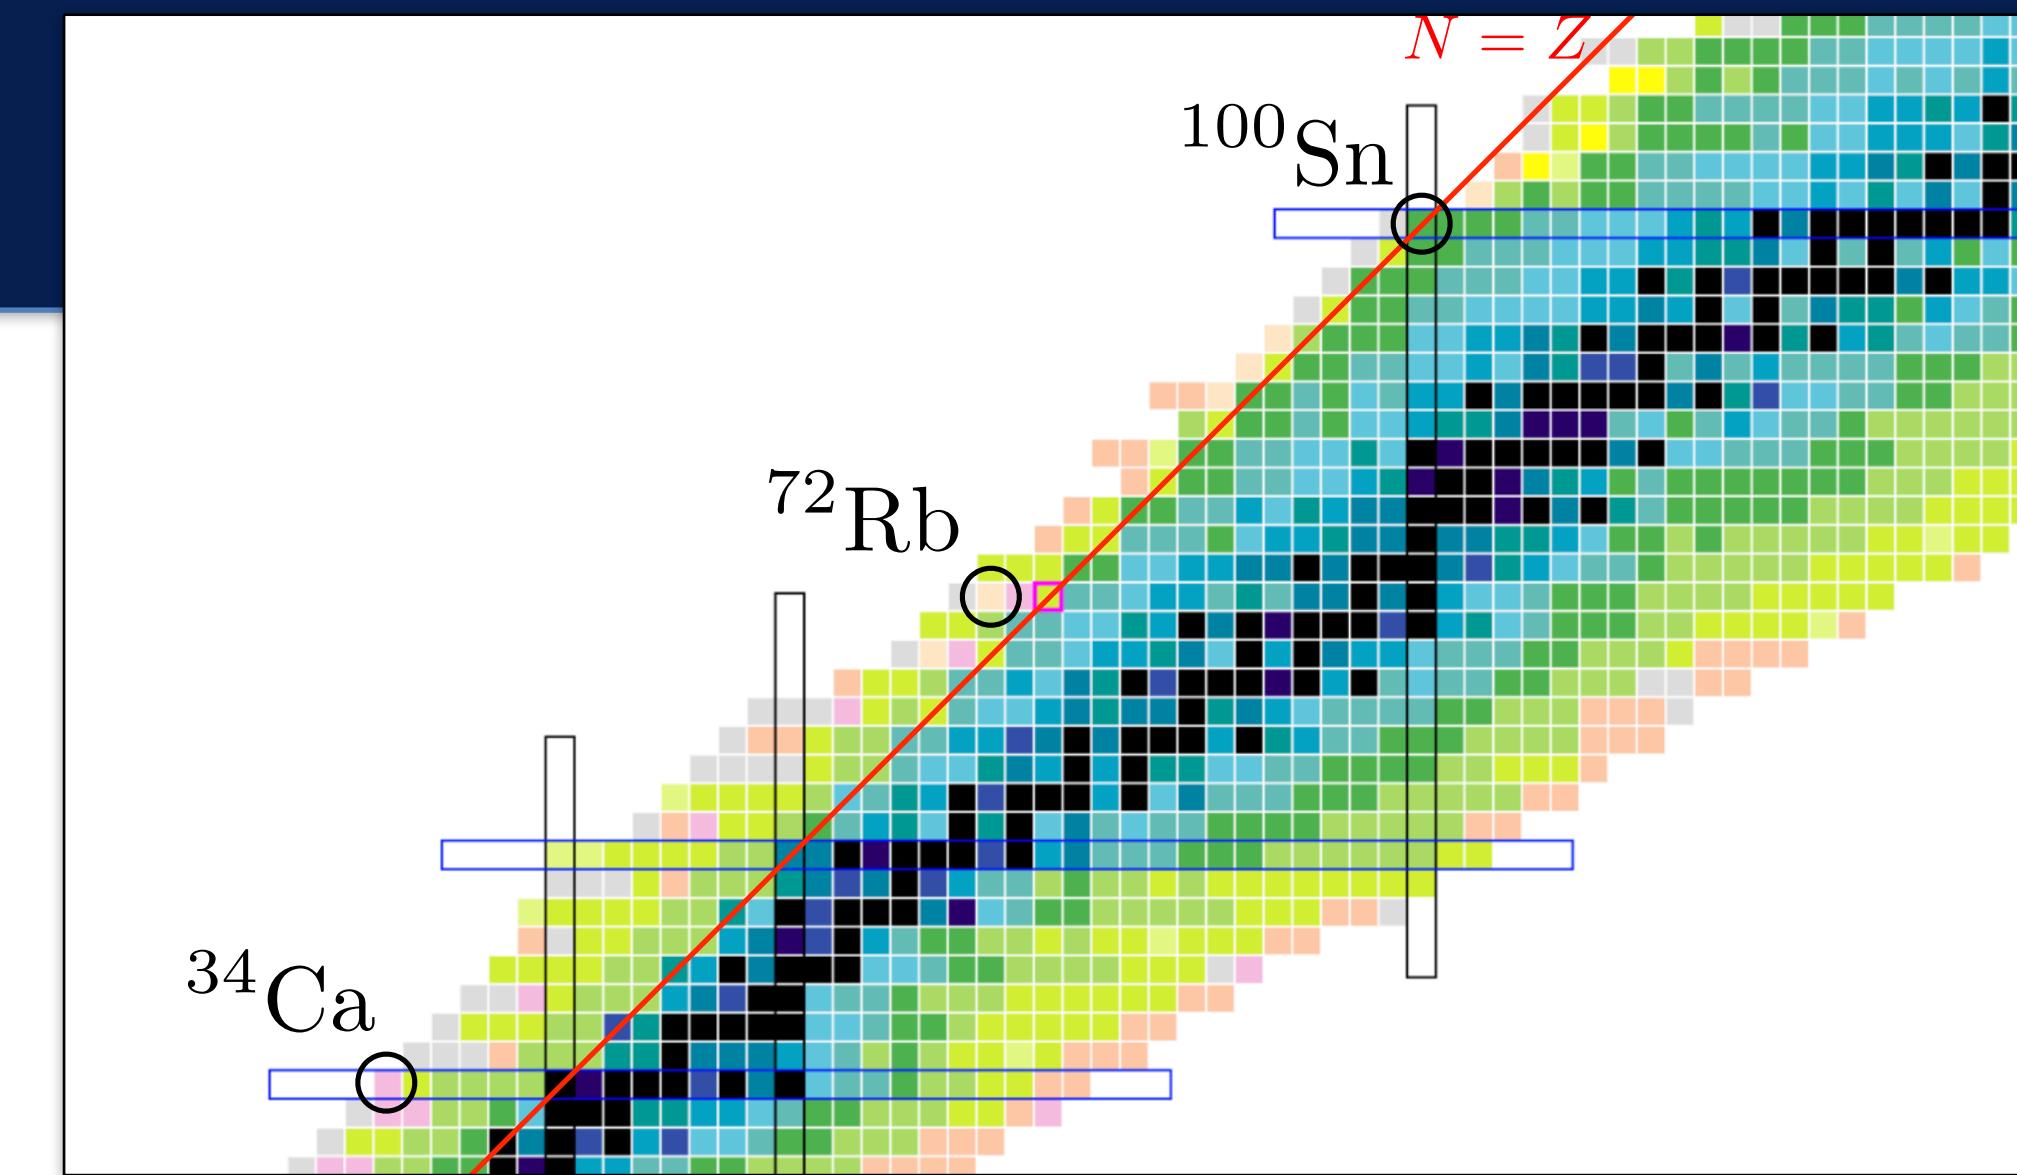

# Day 1 Experiments at FRIB

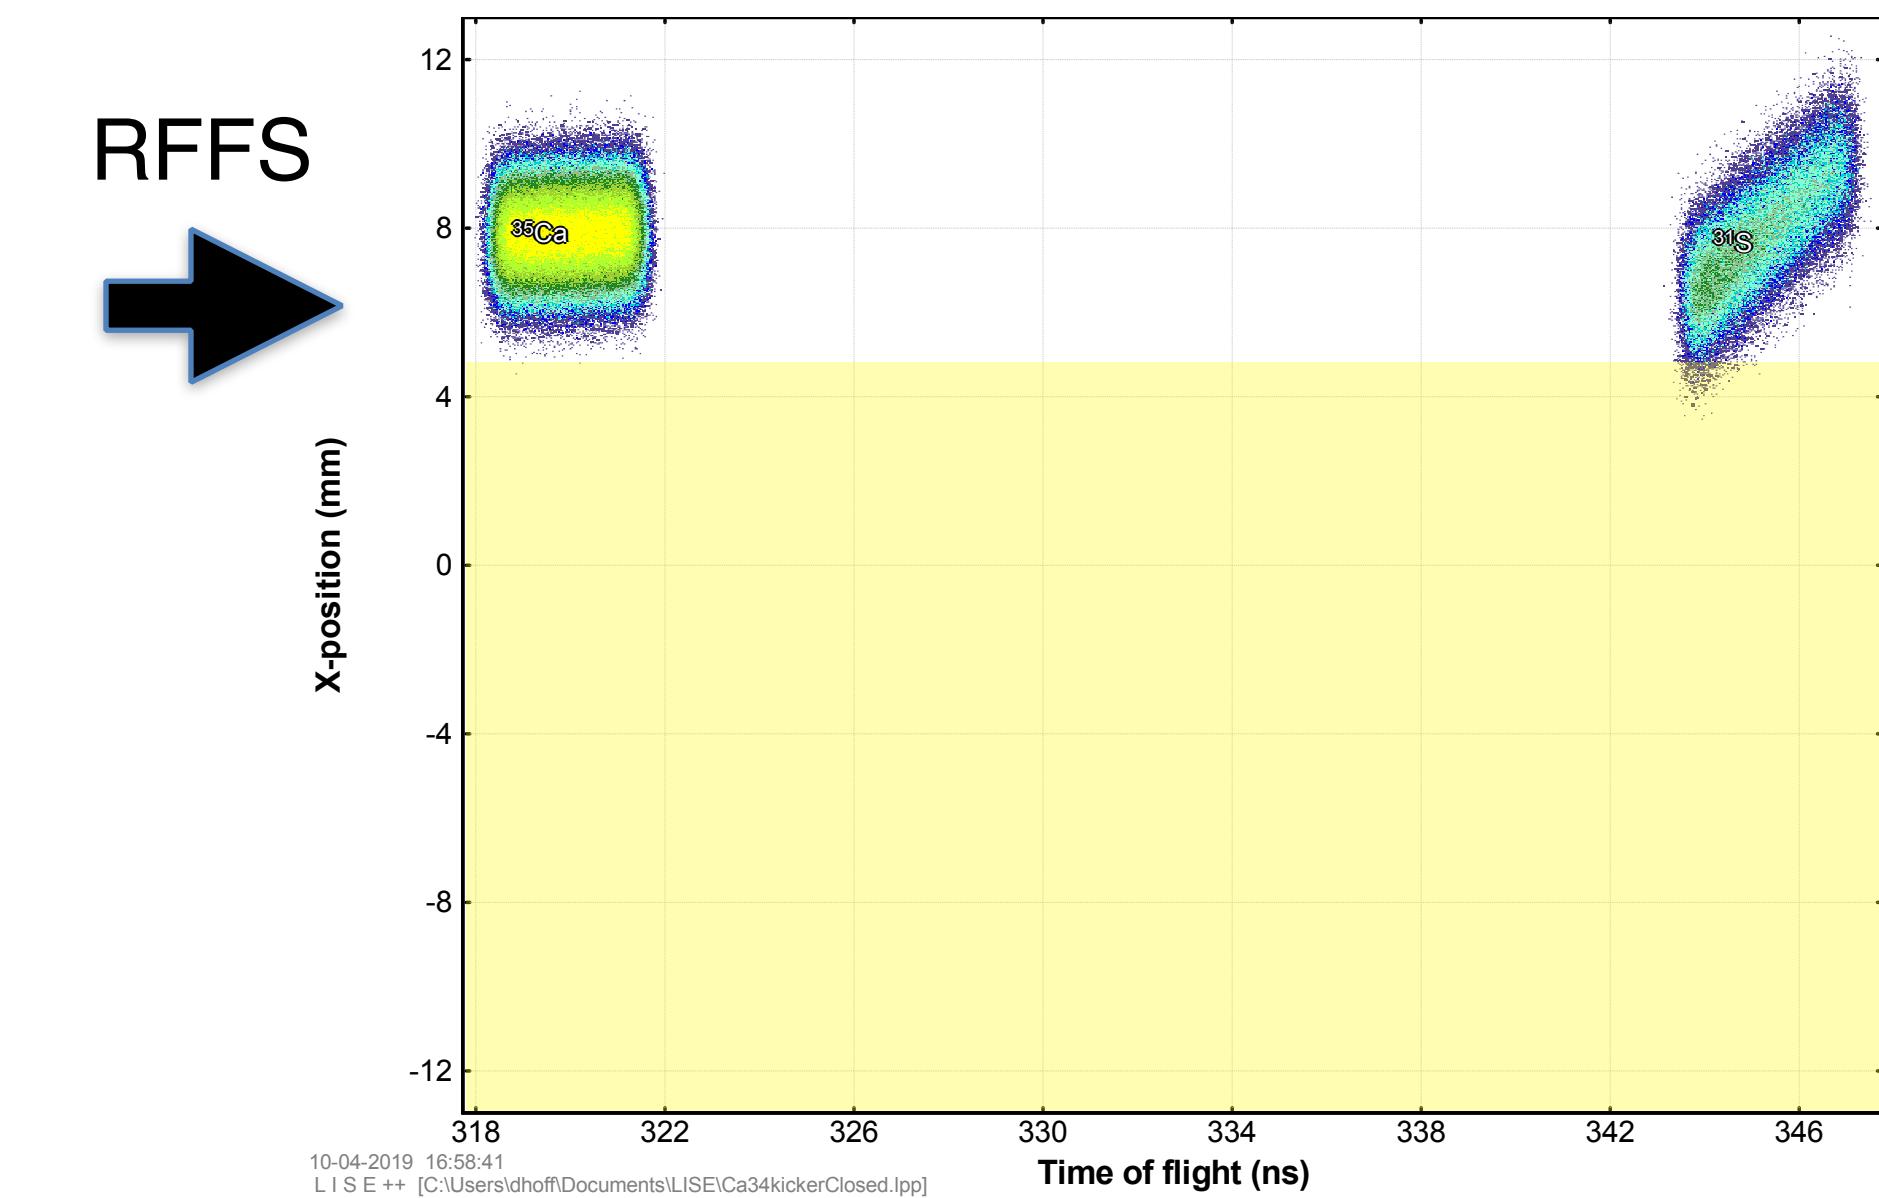

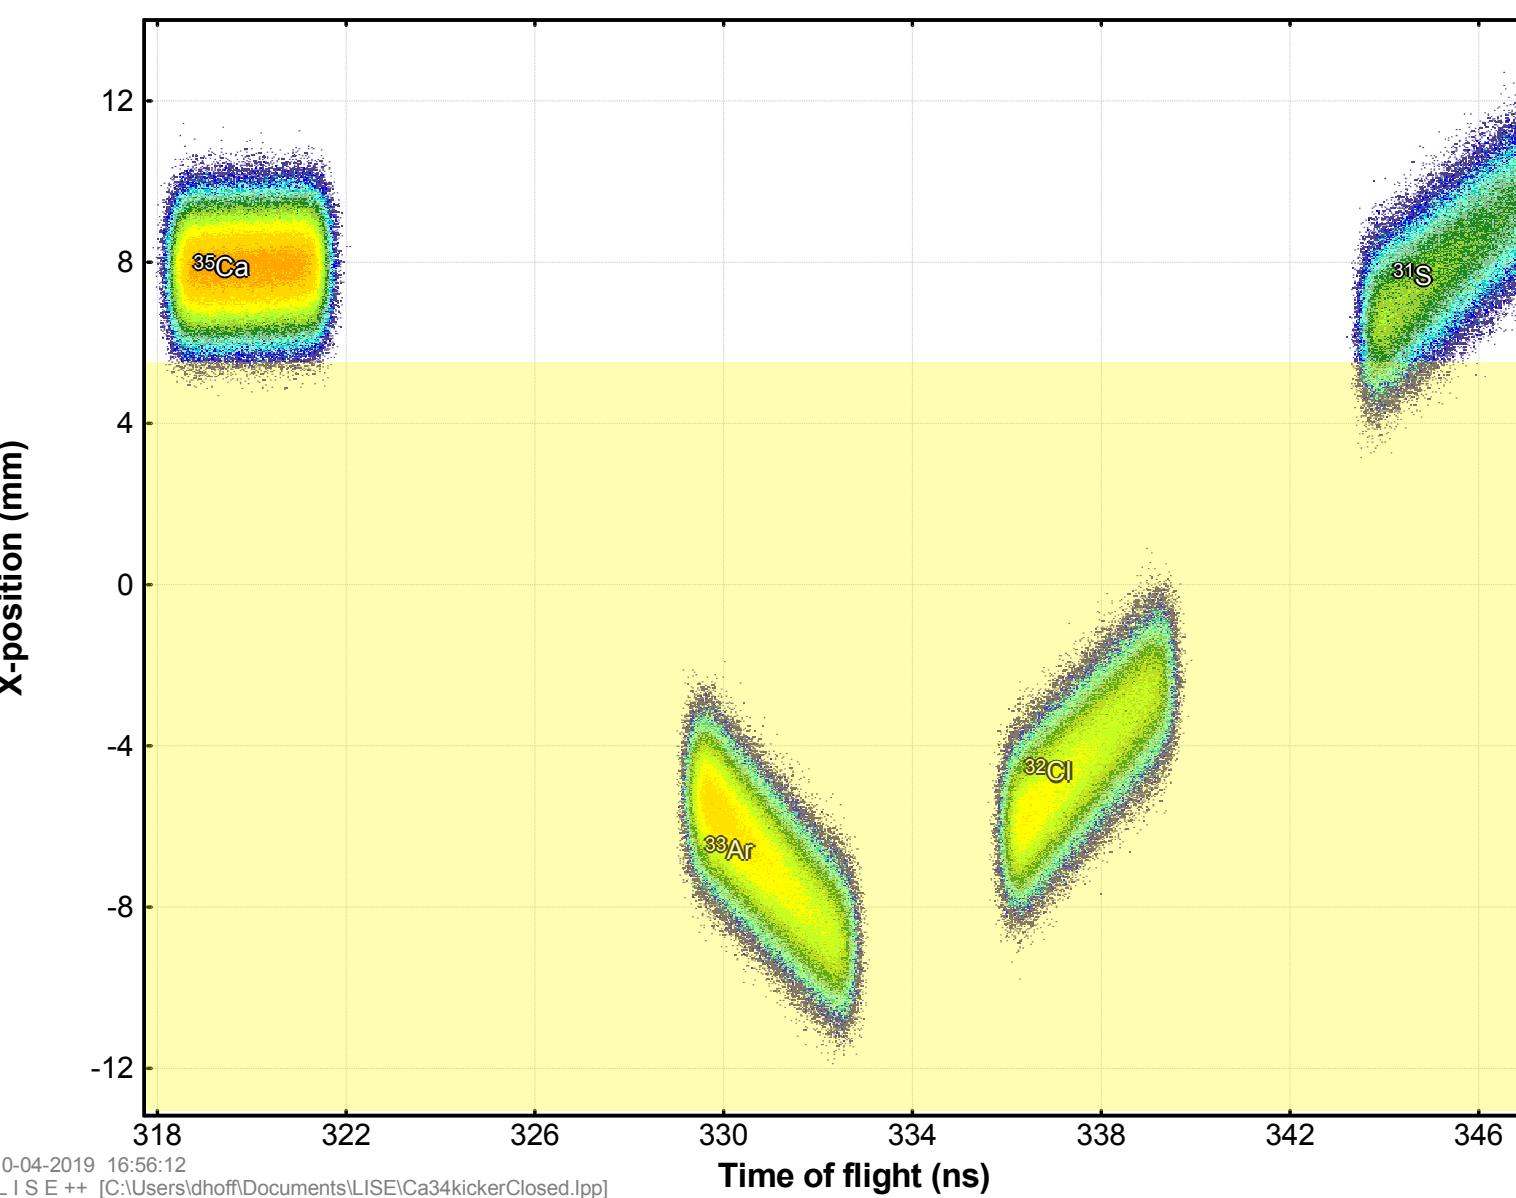

## Invariant Mass Spectroscopy of $^{34}\text{Ca}$

- One nucleon knockout of secondary  $^{35}\text{Ca}$  beam, from  $^{40}\text{Ca}$  primary beam.
- $\sim 1.5\%$  of beam would be  $^{35}\text{Ca}$  without kicker
- $\sim 95\%$  of secondary beam would be  $^{35}\text{Ca}$  after RFFS
- $^{34}\text{Ca} \rightarrow ^{32}\text{Ar} + 2\text{p}$  channel can be measured with upgraded HiRA (10 cm long CsI(Tl)'s) + S800

LISE++ FRIB setup provided by Daniel Bazin

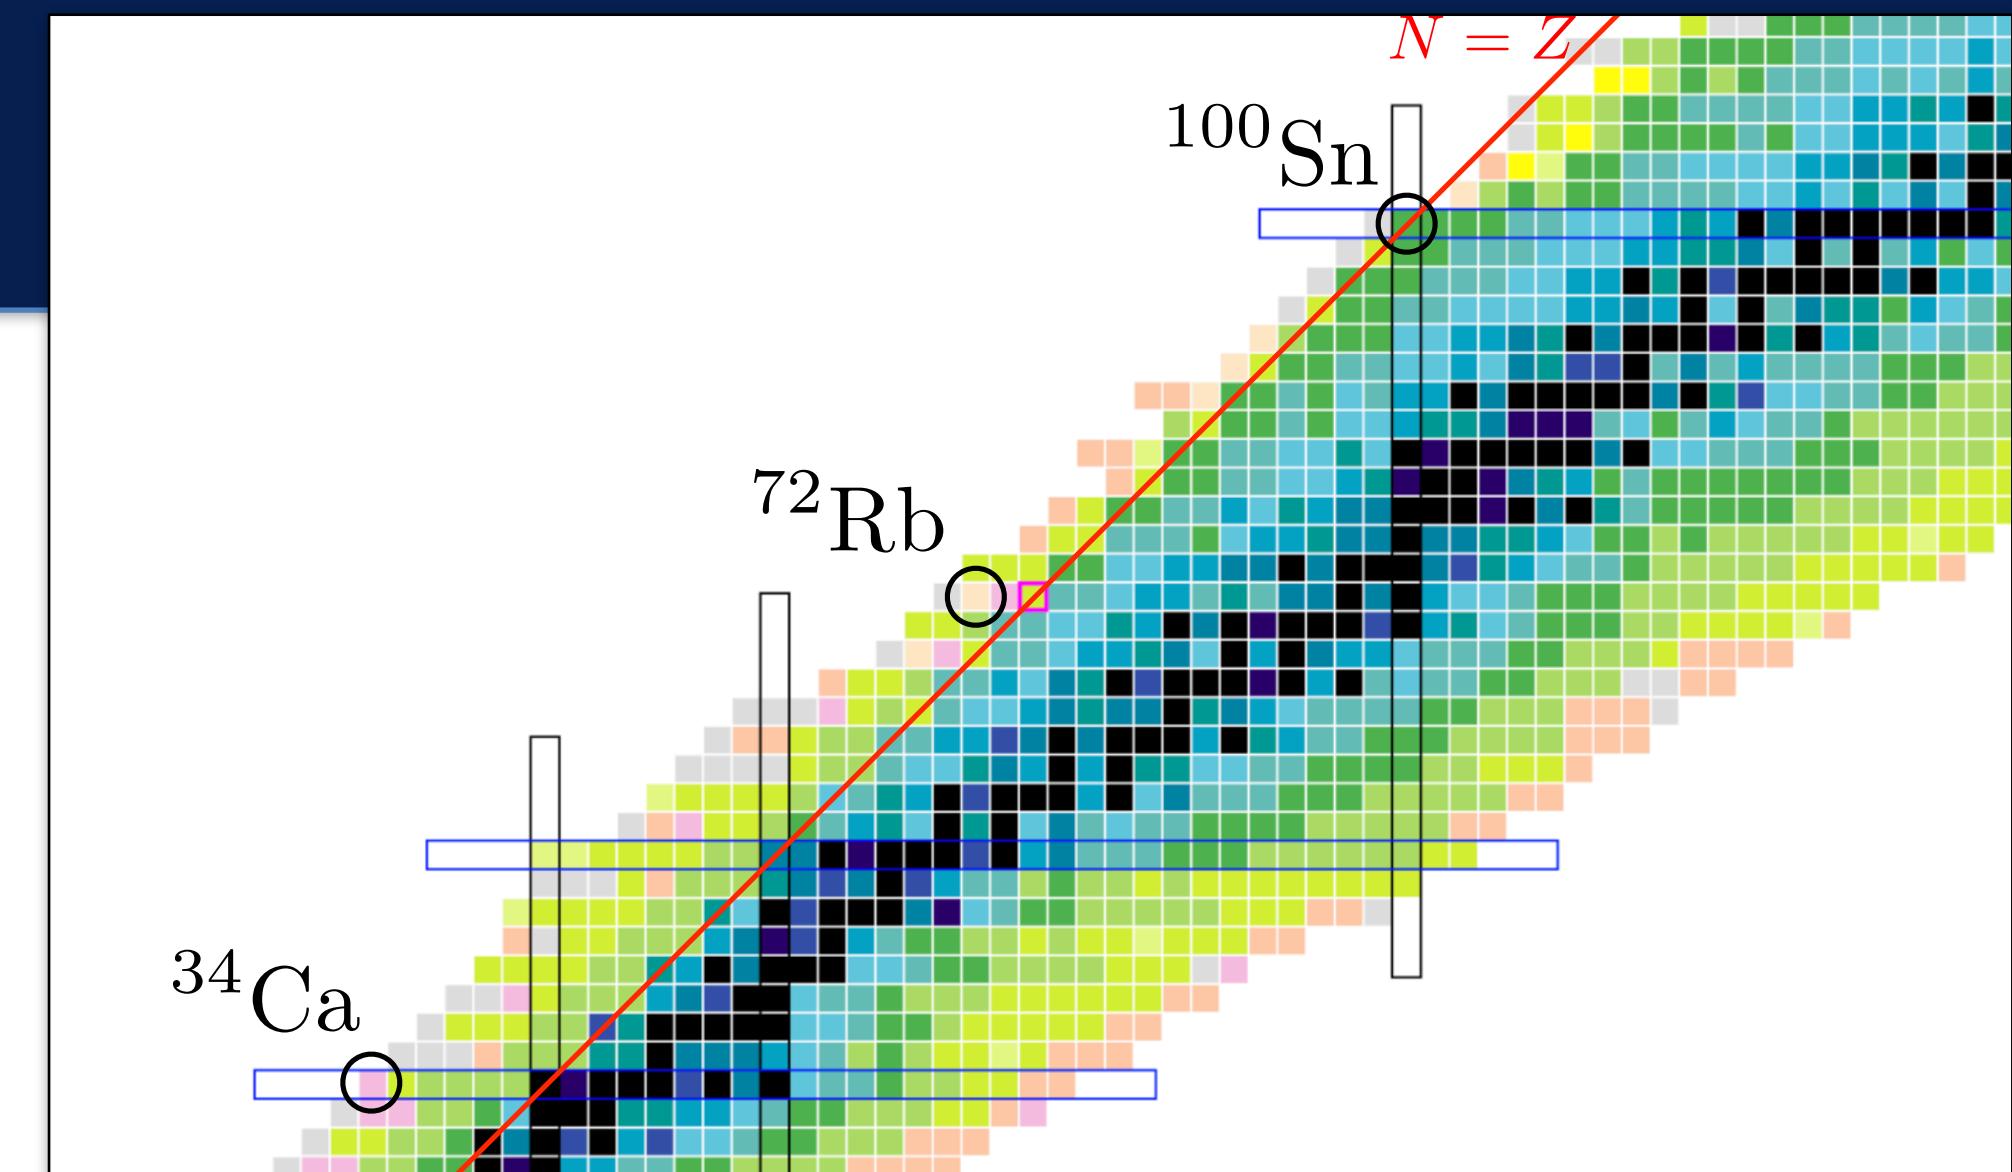

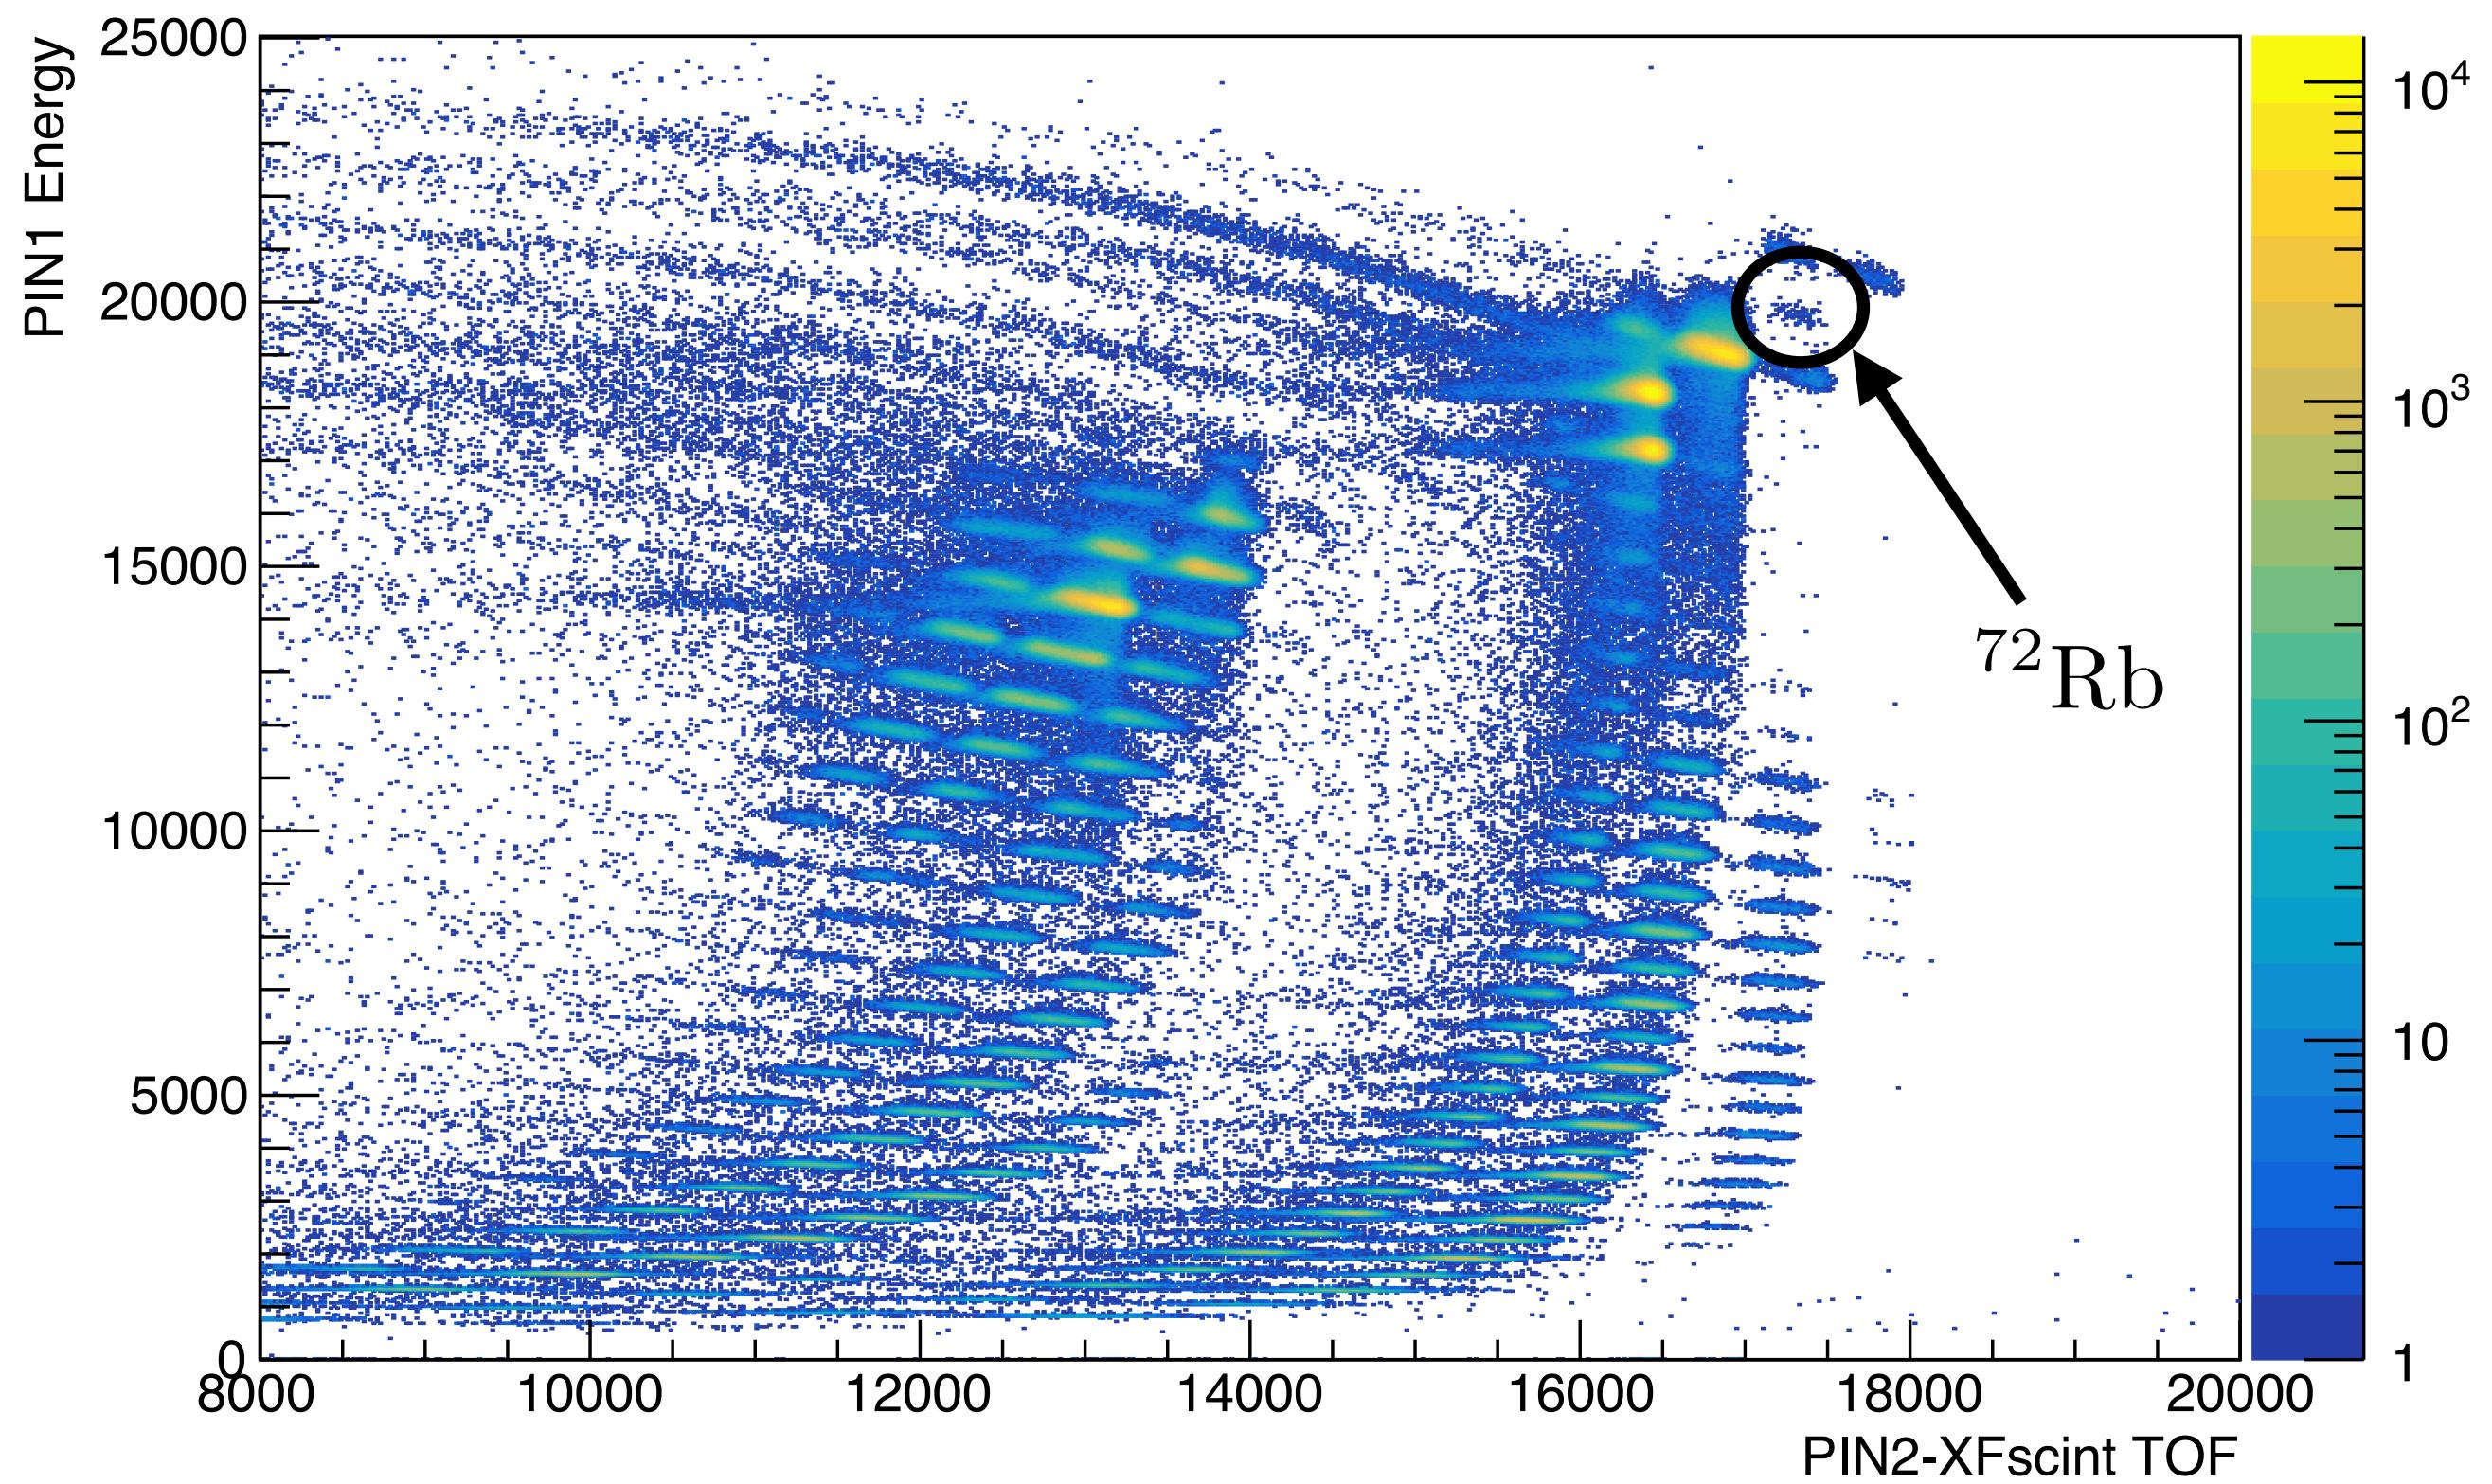

10 kW 140 MeV/u  $^{40}\text{Ca}$  primary beam

# Day 1 Experiments at FRIB

## Decay studies of $^{72}\text{Rb}$

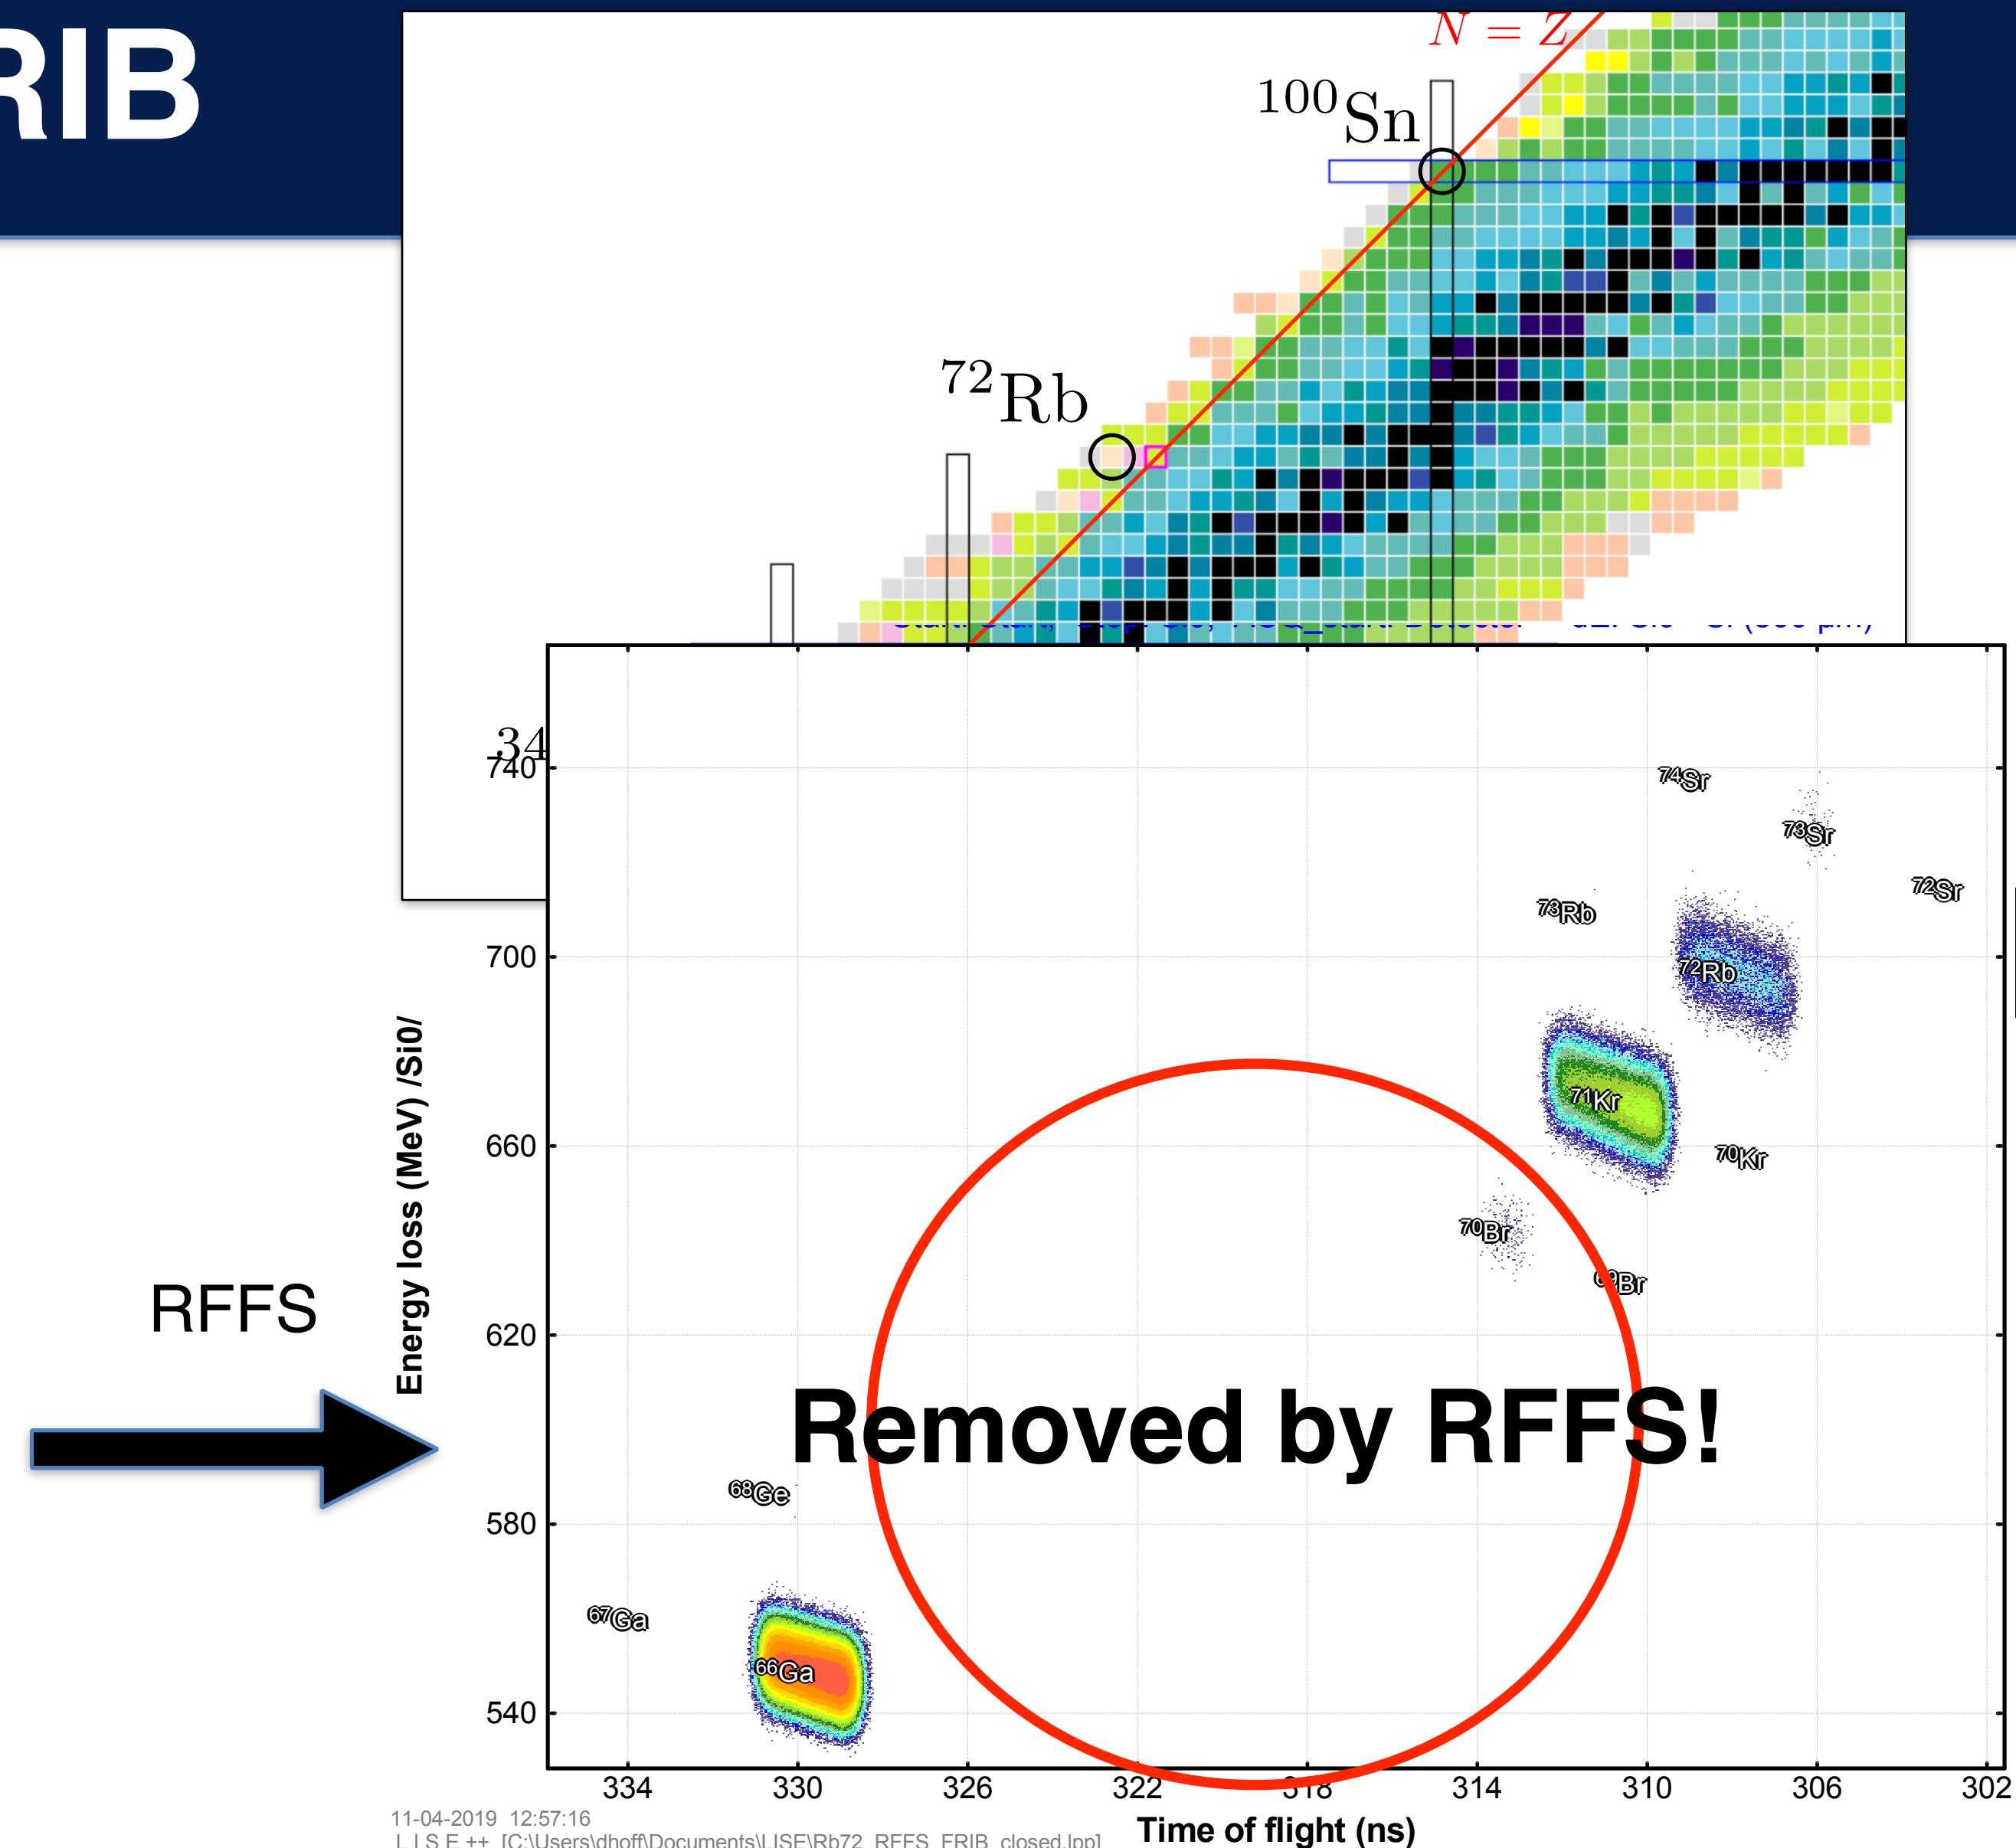

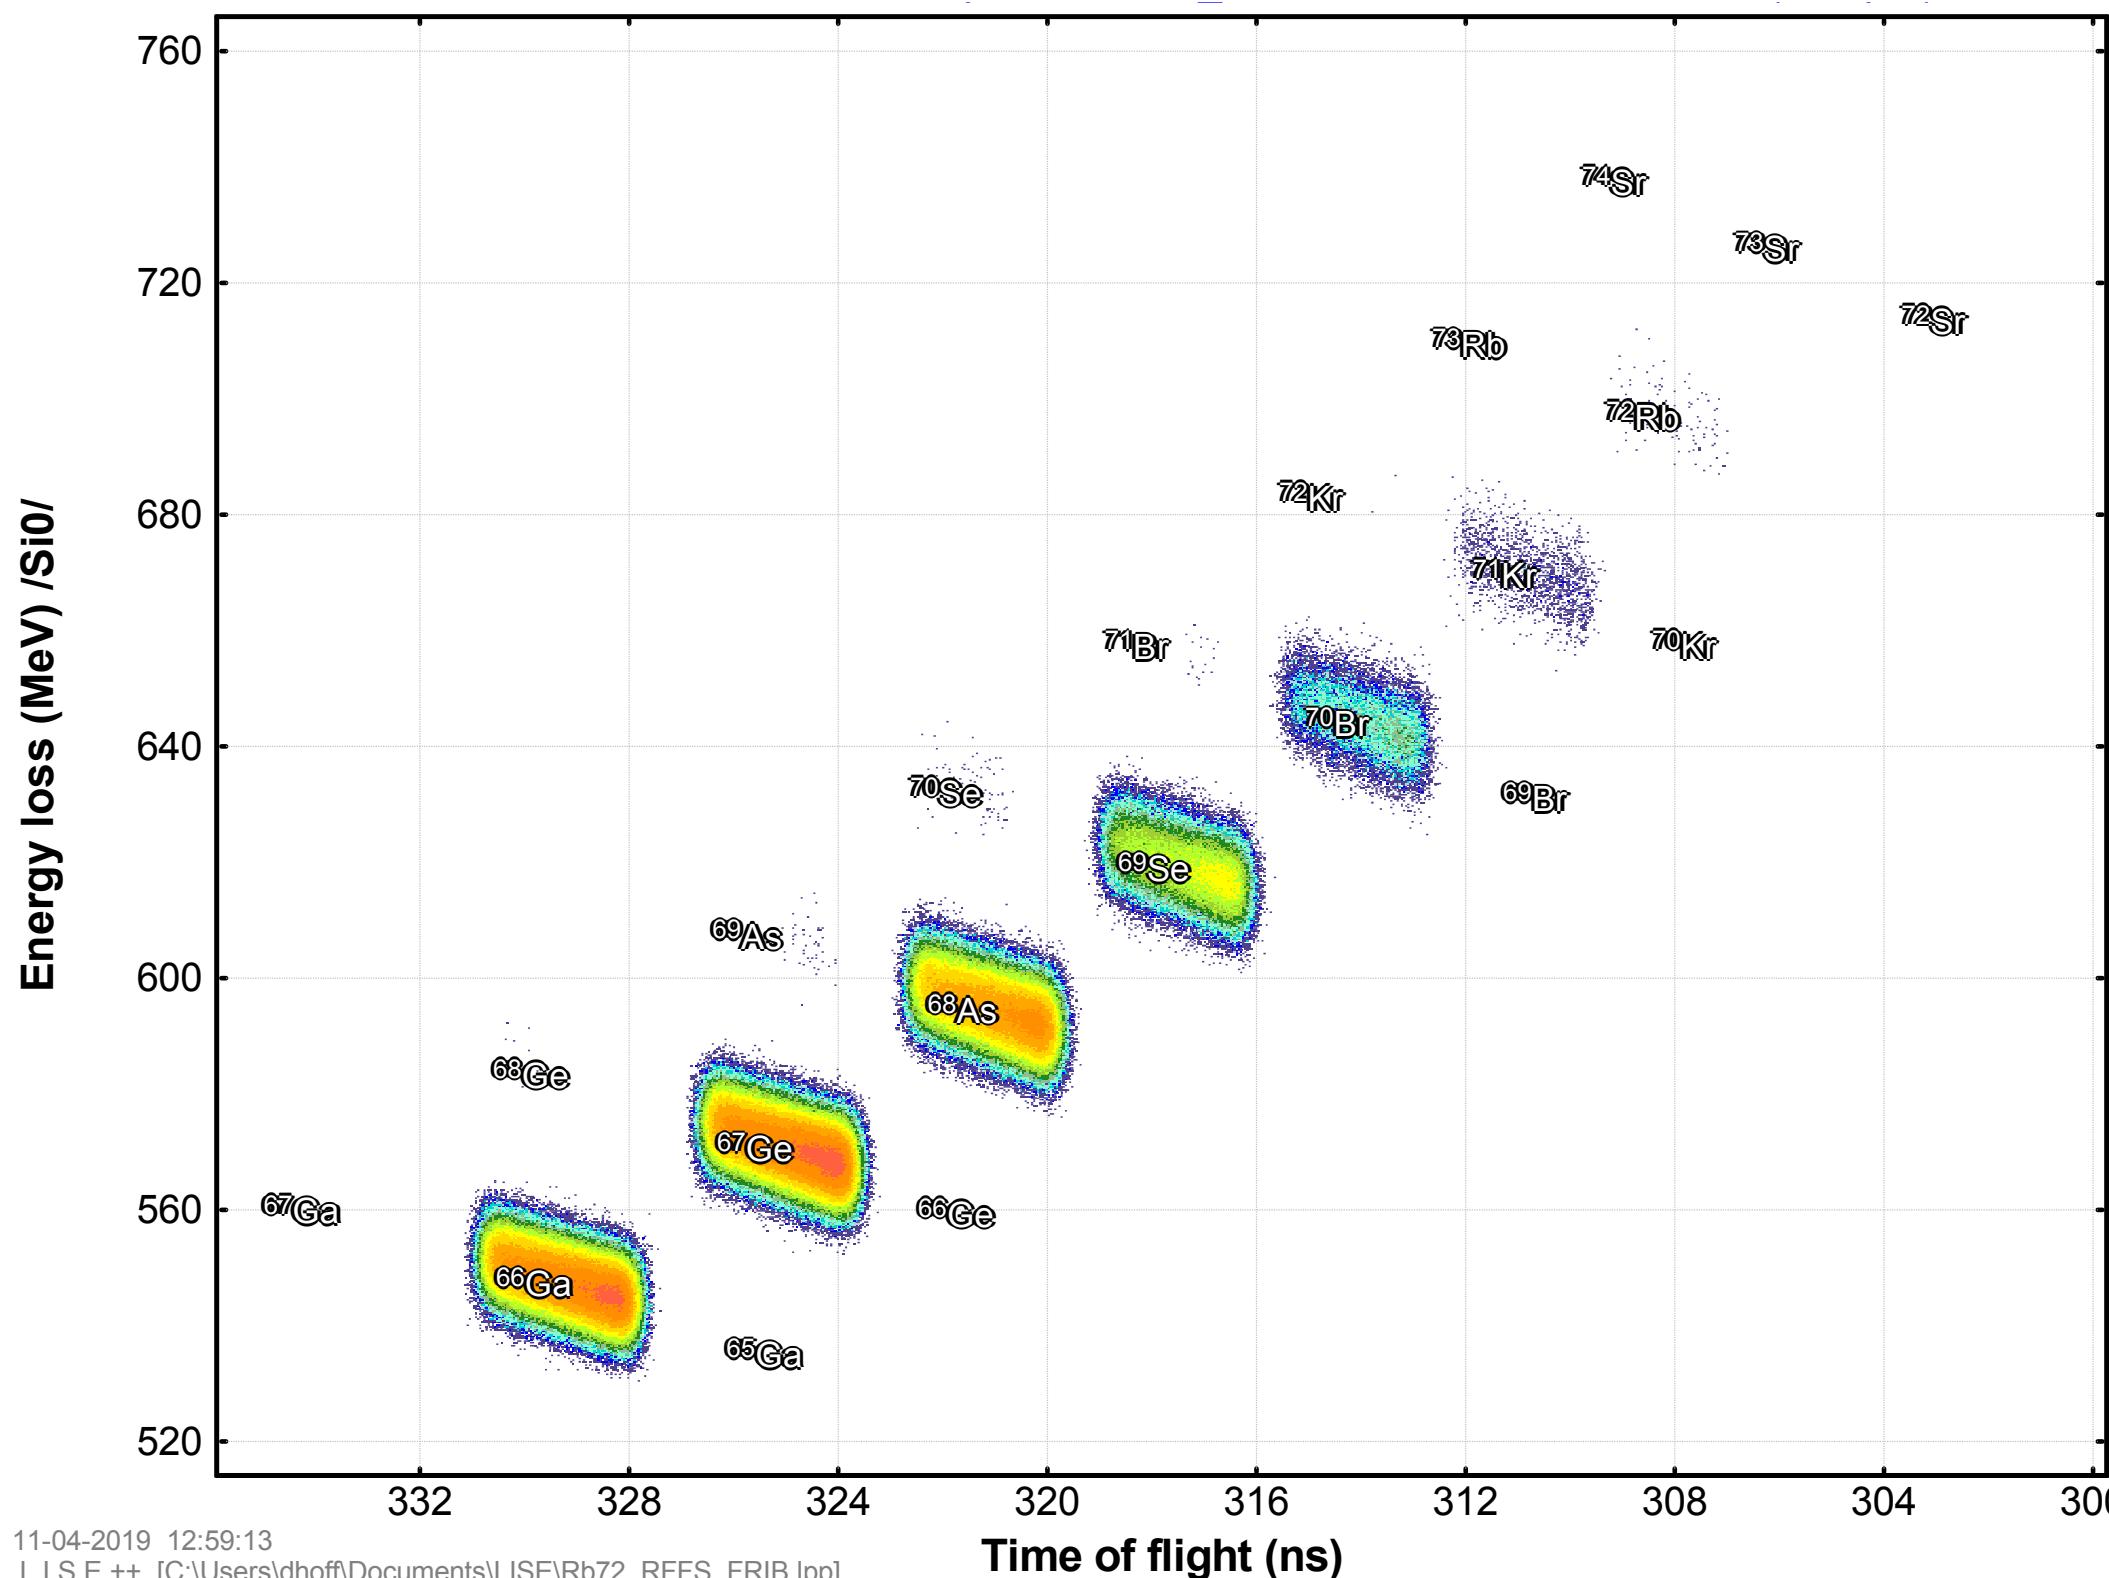

- Observed  $^{72}\text{Rb}$  in  $^{73}\text{Sr}$  run... but too few statistics to extract observables.
- One could run same similar experiment with A1900 focused on  $^{72}\text{Rb}$ .
- With FRIB beam rates, would obtain same number of statistics from week-long  $^{73}\text{Sr}$  run in a matter of hours!

# Day 1 Experiments at FRIB

## Decay studies of $^{72}\text{Rb}$

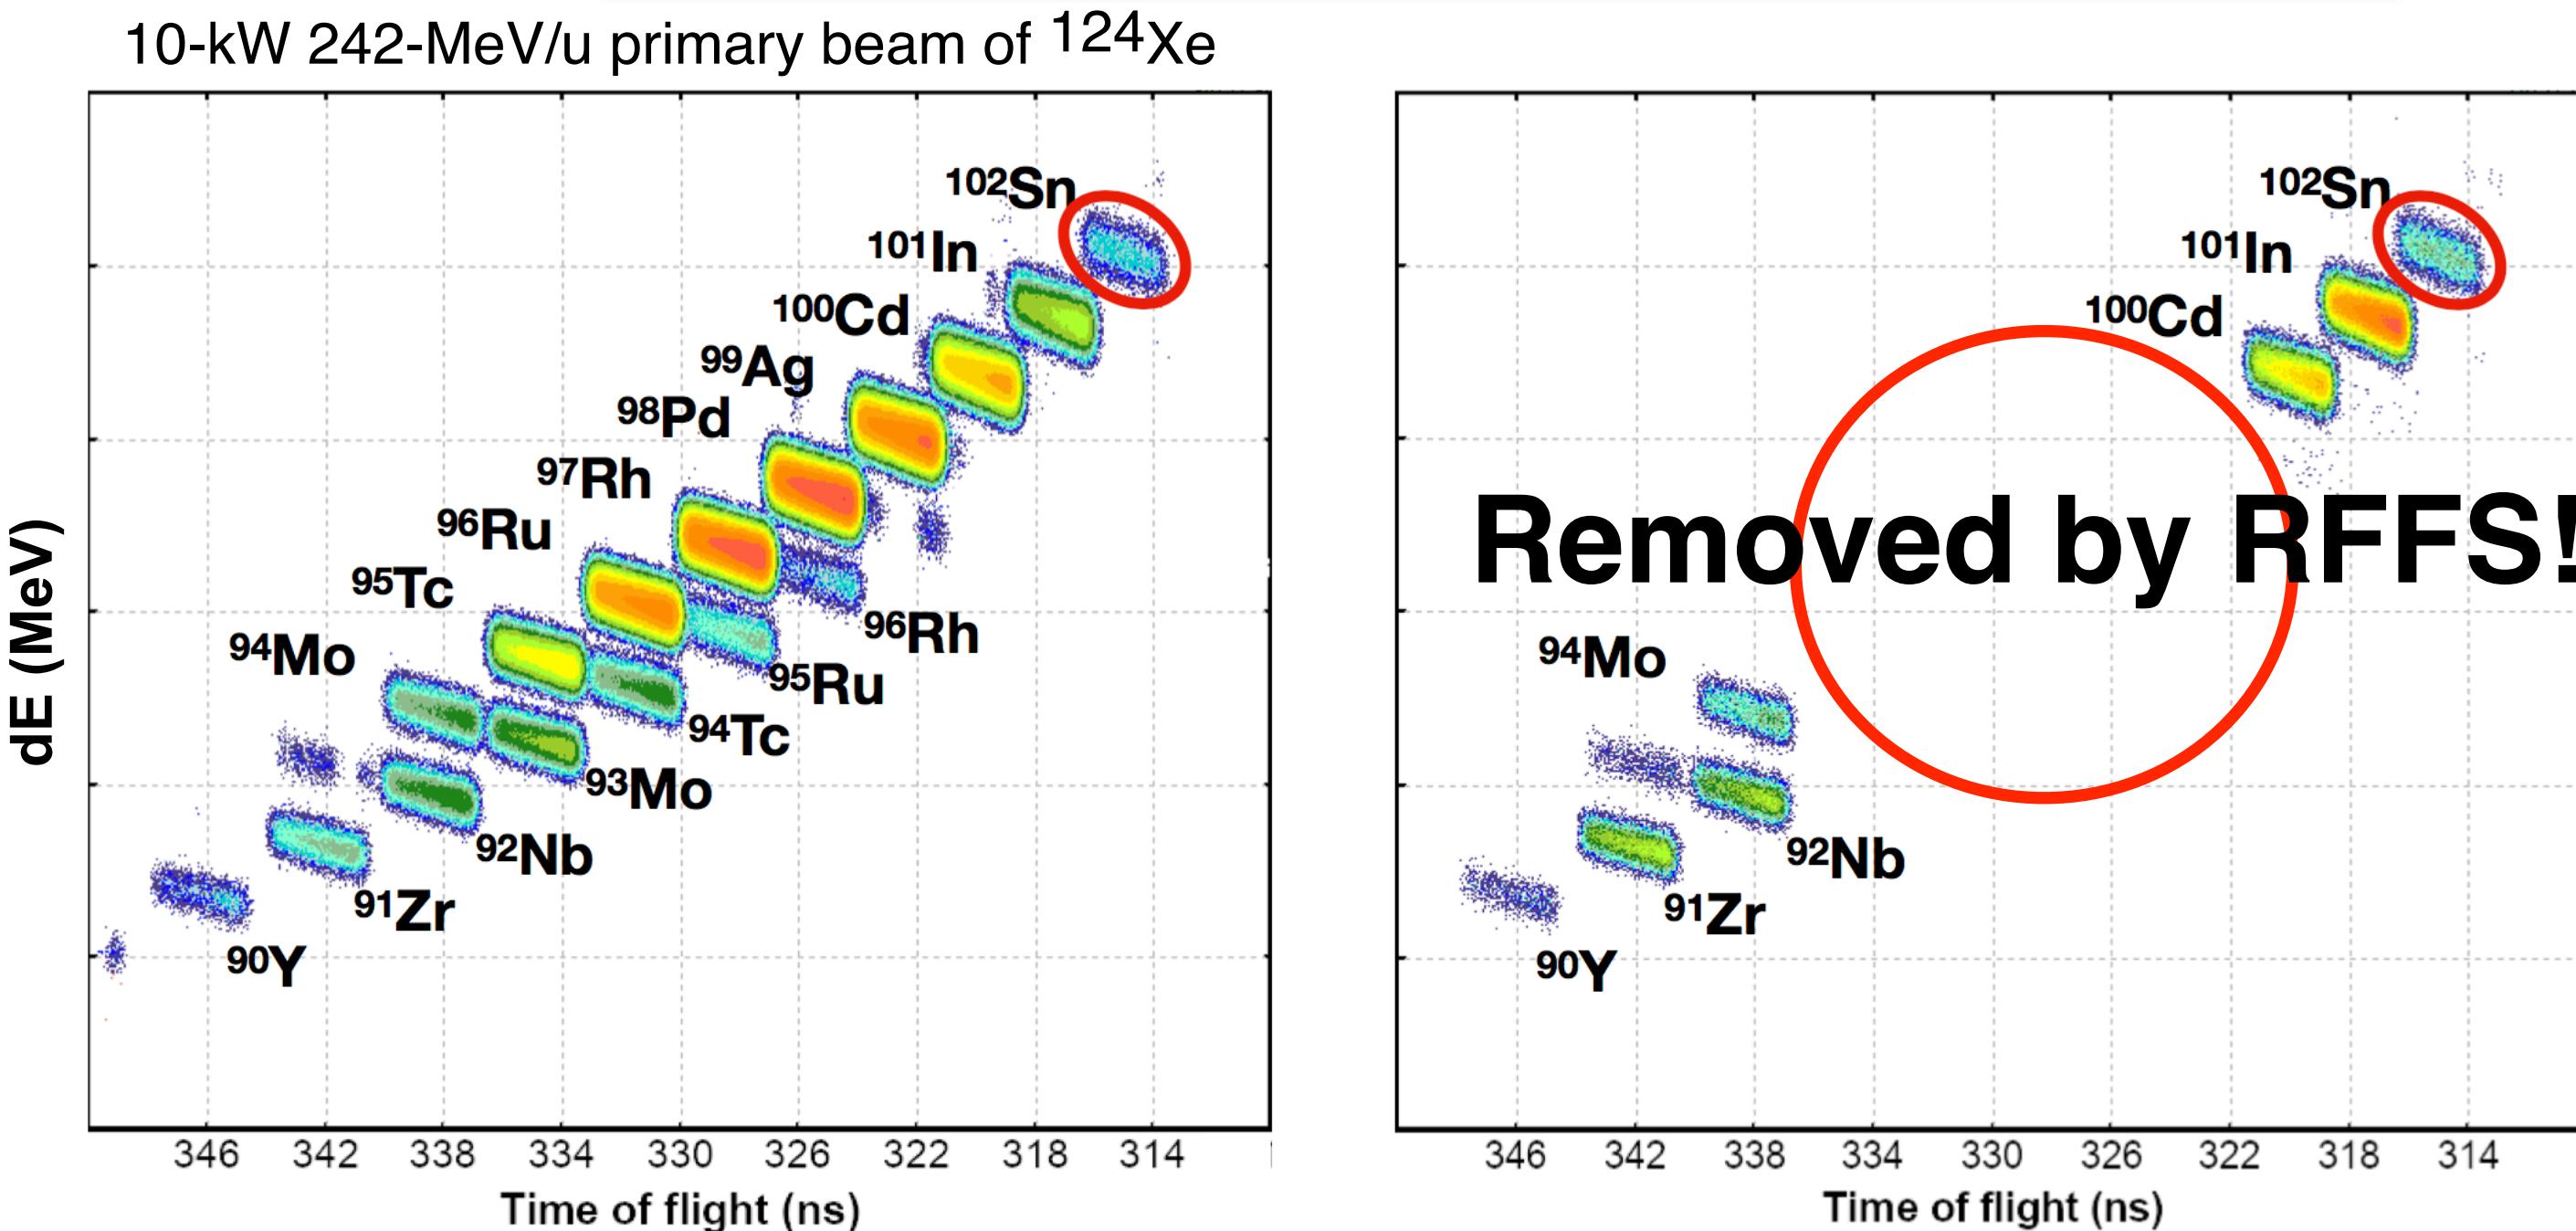

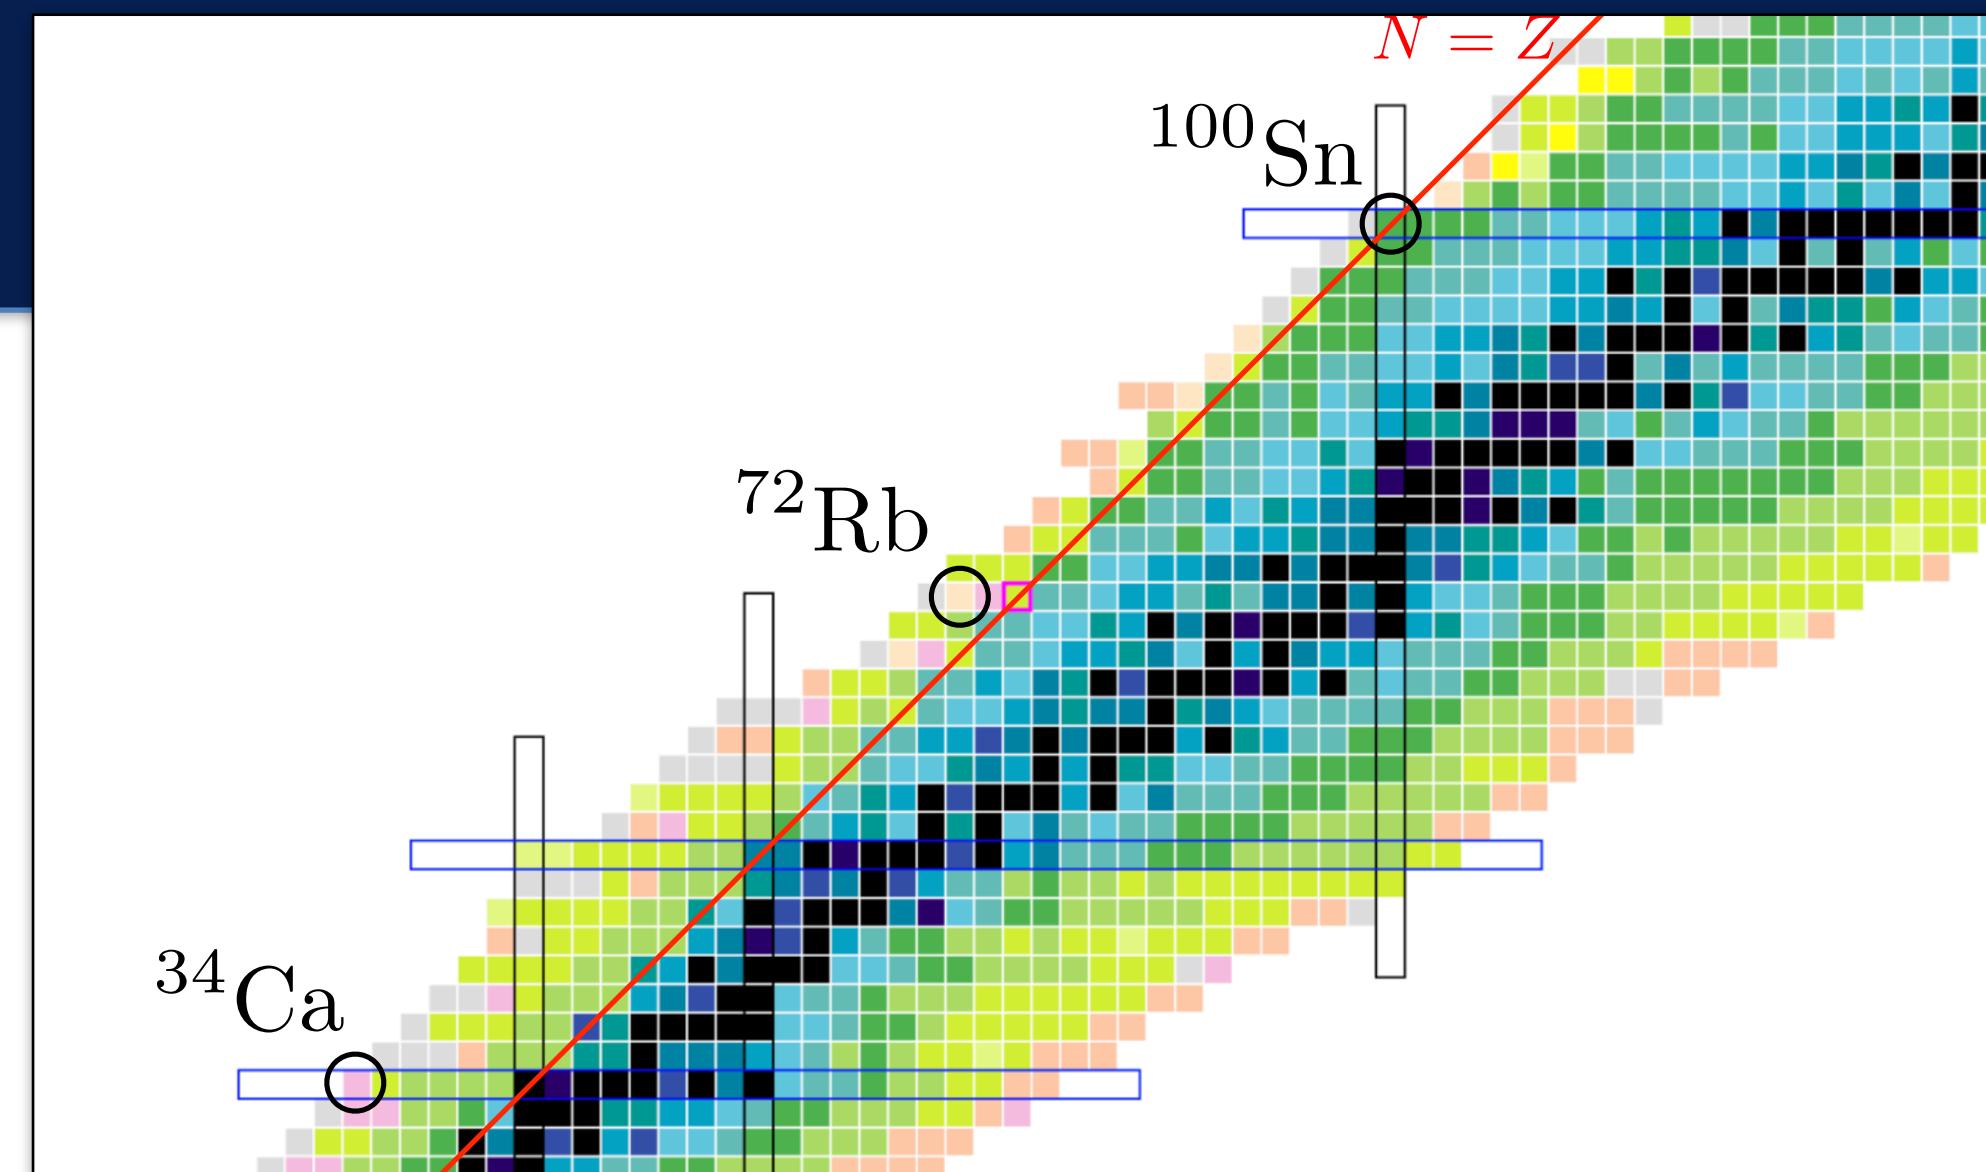

200 MeV/u  $^{92}\text{Mo}$  primary beam fragmented on thick Be target with thick Al wedge

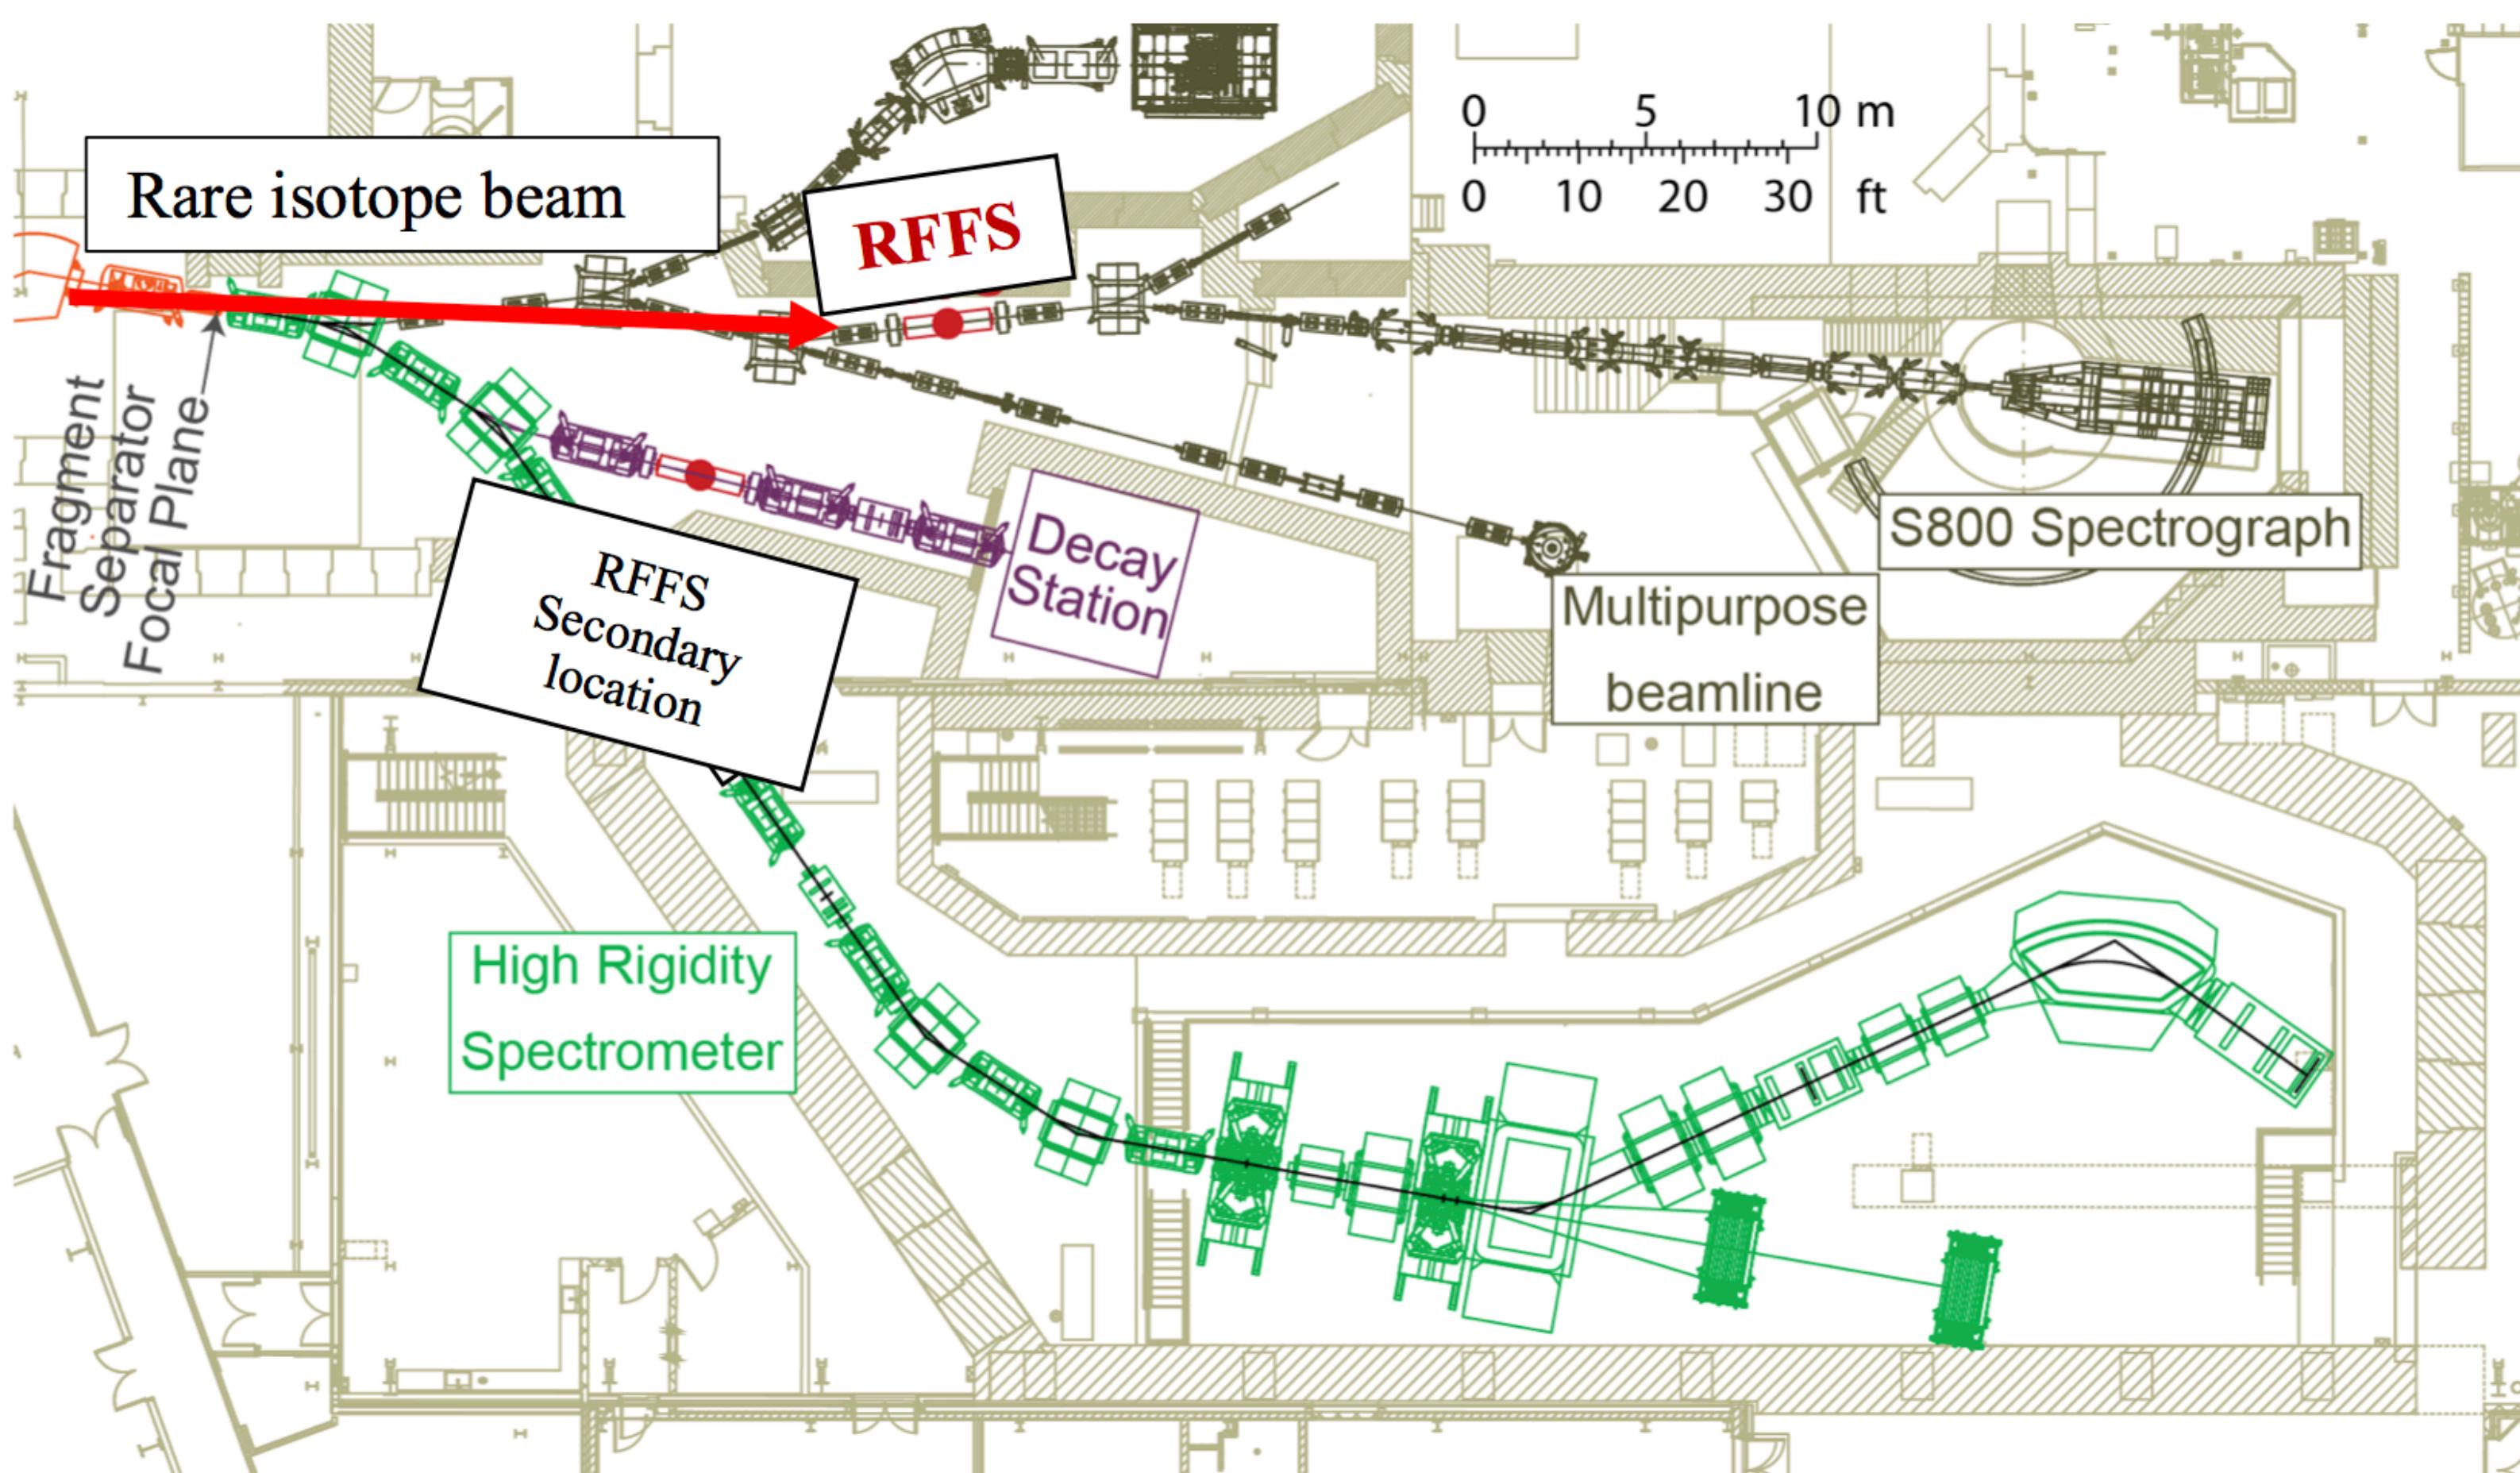

# Day 1 Experiments at FRIB

## Decay studies of $^{100}\text{Sn}$

- Previous experiments only measured  $\beta$ -decay properties.
- To understand shell structure, need to populate higher lying states.
- Higher lying states can be populated by nucleon knockout reactions → **Use  $^{102}\text{Sn}$  secondary beam!**
- Could even do experiments at the endpoint region of the rp-process.

# Outlook

- Preliminary designs for new RFFS already done.
- Many Day 1 FRIB experiments could use new proposed RFSS.
- Outlook looks good!
